With tons of memory

## DECLARATION

The research work embodied in this thesis has been carried out at National Chemical Laboratory, Pune under the supervision of Dr. C. V. Ramana, Organic Chemistry Division, National Chemical Laboratory, Pune - 411008. This work is original and has not been submitted in part or full, for any degree or diploma of this or any other university.

Though only my name appears on the cover of this dissertation, many others have contributed to its production. I therefore take this opportunity to thank all those people who have made this thesis possible and because of whom my PhD experience has been one that I will cherish for the rest of my life.

My hearty thanks to my advisor, Dr. C. V. Ramana. I have been extremely fortunate to have an advisor who not only educated me in Chemistry but also taught me discipline and shown unique ways to achieve my goals. This has helped me overcome many obstacles along the path to my PhD. His humanity and scientific curiosity were a constant source of inspiration. I shall never forget his enthusiasm for team work and strong work ethic. I am grateful to have been part of his group where I learned the scientific tricks of chemistry as well as of life.

I highly thankful to Dr.M. V. Deshpande and his group, especially Dr. Santhosh Tupe for his unhesitating help and valuable suggestion for completion of thesis and also Ms Duhita, Ms Neha and Ms Gouri.for antifungal activity work. I also thankful to Prof Alexei Degterev and his group for anticancer collaboration work.

I also thank the former Head of the OCD, Dr. Ganesh Pandey, and the Head Organic Chemistry Division, and the Director of NCL for providing infrastructural facilities. I gratefully acknowledge the valuable suggestions and timely help of Dr. D. S. Reddy, Dr. Srinivas Hotha, Dr B.L.V. Prasad, Dr. Vanka KumaDr. S.P. Chavan, Dr. Thulsiram, Dr. S.B.Maske, Dr. Borate, and r. Suggestions offered during assessments and other presentations, by scientists namely, Dr. S.P. Chavan, Prof. D. D. Dhavale, Dr (Mrs.) Viashali Shinde, Prof S. B. Waghmode and Prof. M. G. Kulkarni are also gratefully acknowledged.

I am thankful to my teachers Mrs Durga kumari madam, Mrs Hemalata madam and Dr Ramadevi from St Gabriels High school and Mr. Laxmaiah, Mr.T. mallesham at primary school Bhanajipet, for their inspirational teaching, honorable ethics and firm discipline. I am highly thankful to Prof H. Suryaprakash Rao, Prof Sambashiva Rao(late), Prof Balamanimaran Prof B. B. Das, Dr C. R. Ramanathan from Pondicherry University, for their sincere efforts and motivating towards research during my stay at the Chemistry Department, University of Pondicherry.

I sincerely thank Mrs. Kathrine Raphel, Mrs. Pooja Kulkarni and all OCD office staff for their cooperation. Help from the spectroscopy, analytical and mass group is gratefully acknowledged. I sincerely thank Dr. Rajmohan, and his group Sumesh and Srikanth. For HRMS Mrs. Santhakumari, Mr Swamy and Mr Sandeep (IISER Pune) for their unhesitant support and assistance.

I would like to offer my special thanks to my friends Dharmaraju, Dr. Santhosh Reddy, Dr. Vilas, Mahender, Chandrababu Naidu, Suneel, Manoj, Ramesh, Bhanu, Anjaiah nayak, Kumar, Anji (thoka), Krishna, Narsimha Reddy, and beloved seniors Dr B. Srinivas, Dr. Rajendar Reddy, Dr. Sreedhar Reddy, Dr Raman, Dr. Swaroop, for their love, affection and for creating family atmosphere.

I greatly thankfull to families of my friends Vilas-Sunitha, Rajender reddyYogitha vadina, Santhosh-Uma Sai and Srinu-Sravya, Srinu anna-rajitha vadina, Raju anna (bio) for creating family atmosphere.

I gratefully acknowledge the training and support extended by my senior colleagues Dr. Srinivas, Dr. Indu, Dr. Chandra Kiran, Dr. Sharad, N. Raghupathi, Dr. Nageshwar Reddy, Dr. Kulbhushan, Dr. Giri, Dr. Pandey, Dr. Pitambar, Dr. Rahul, Dr. Sachin, Dr. Mondal, Dr. Rosy, Dr. Anuj, Dr. Rehman, Dr. Sahoo, Dr. Vikhe and B. Senthil kumar, and special thanks to Dr. Rita, who taught me various techniques and encouraged me at several point of time during the tenure as a PhD student. I would like to thank all my colleagues for always maintaining cheerful and healthy work environment inside as well as outside the Lab. My special thanks to Narendraprasad reddy, Srinivas, Venkannababu and Friedi,who work with me and helped in completion of thesis. I thankful to Mangesh, Sridhar, Yogesh (goru), Ketan, Jitu, Paresh, Atul, Ravindra, Ajay, Dinesh, Anuradha, Anand, Mahesh(P), Vivek, Mahesh(S), and Reenamai, Gowri and Reshma with whom I shared my most precious moments during my PhD .

I also consider myself blessed in that I got to spend a major chunk of my time at NCL with all telugu mithra mandali Venu and Chaithanya, Dr. Ravi, Durgaprasad, Shiva, Janakiram, Narsimha Rao Kanna, Bogesh, Ramireddy, Bala, Rambabu, Chaithanya krishna, Shanthivardan, Hanuman, Laxmi Prasad, Deva datta, Innaiah, Srikanth, Nagendra, Trinadh, Suresh, Seetharam sing, Sathish, Kasinath, Naresh killi, Hari, Tharun, Eeswar, Nookaraju, Dr Sudhakar, Dr Eshwar, Dr.srikanth (Late), Dr. D. Srinivas, Dr. Ramesh and Dr. V. Srinivas Rao. They have always been and will continue to be an inspiration to me. I always enjoy their company and they are my strength for many things. I am luky to have such a big family, which I have got kind gift in NCL. I also thank my friends in IISER. Krishna, Ravi kiran, Venkateshwar rao, Kishor, Bapu, Jagadhesh, Sathesh. I always remember most precious moments which spent with you all during Vijayanama Ugadi celebration. The care and emotional support of these people has been tremendous and they have been a family to me away from home.

My family is always source of inspiration and great moral support for me in perceiving my education, I used thank god of almighty for providing me such a beautiful family. The words are insufficient to express my sense of gratitude for my family. Though, I take this opportunity to my sense of gratitude to my parents Muthamma (mother) and Narsaiah (father) for their tons of love, sacrifice, blessings, unconditional support and encouragement. I express my deep and paramount gratitude to my elder brother Yellaiah who is my first teacher, for his immeasurable love and affection. I always feel that I am lucky to have brother like him. Without his constant support, encouragement, positive thinking and inspiration I cannot stand with this dissertation. When I successfully complete this thesis, he is no more to see my success. I hope his blessings will give me the strength and will continue to guide my future. Whatever I am and whatever I will be in future is because of their enormous blessings, hard work, commitments to my ambitions, and their selfless sacrifices. Words fall short to thank my second brother Srinivas, sisters Vijaya and Sunanda, my
sister in laws Anjamma ans Rajitha and my brother in laws Ramesh and bhasker for their never ending encouragement, support and love. I am lucky to have wonderful nephews Aravind, chintu, pintu and vinnu, lovely niece Shirisha, Akhila, Ammulu and Laksmi prasanna who are the full of happiness, Joy and Curiosity, everlasting cheerfulness in my life. I always enjoy their company even at short stays at home

I also thankful to CSIR, New Delhi for the financial assistance in the form of fellowship. At last but not the least, I thank whole heartedly, the omnipotent God, the illimitable superior spirit, for the strength and determination to put my chin up when faced with hardships in life.

## DEFINATIONS AND ABREVIATIONS

| Ac | - | Acetyl |
| :--- | :--- | :--- |
| $\mathrm{Ac}_{2} \mathrm{O}$ | - | Acetic anhydride |
| AcOH | - | Acetic acid |
| BSA | - | N,O-Bis(trimethylsilyl)acetamide |
| Bu | - | Butyl |
| ${ }^{\text {tBuOH }}$ | - | Tertiary butyl alcohol |
| Cat. | - | Catalytic/catalyst |
| DCM | - | Dichloromethane |
| Conc. | - | Concentrated |
| DMP | - | 2,2'-Dimethoxypropane |
| DMF | - | N,N-Dimethylformamide |
| DMAP | - | N,N'-Dimethylaminopyridine |
| DMSO | - | Dimethyl sulfoxide |
| Et | - | Ethyl |
| EC | - | Effictive concentration |
| HRMS | - | High Resolution Mass Spectroscopy |
| IBX | - | 2-Iodobenzoic acid |
| Liq. | - | Liquid |
| Me | - | Methyl |
| MIC | - | Minimum Inhibitory Concentration |
| NMR | - | Nuclear Magnetic Resonance |
| piv | - | Pivoloyl |
| Py | - | Pyridine |
| $p$-TSA | - | para-Toluenesulfonic acid |
| Ph | - | Phenyl |
| $i$-PrOH | - | iso-Propanol |
| rt | - | Room temperature |
| Sat. | - | Saturated |
| TBAF | - | Tetra- $n$-butylammonium fluoride |
| THF | - | Tetrahydrofuran |
| TMSOTf | - | Timethylsilyl trifluromethanesulfonate |

Abbreviations used for NMR spectral informations:

| br | Broad | q | Quartet |
| :--- | :--- | :---: | :---: |
| d | Doublet | s | Singlet |
| $m$ | Multiplet | t | Triplet |

## GENERAL REMARKS

- ${ }^{1} \mathrm{H}$ NMR spectra were recorded on AV-200 MHz, AV-400 MHz, JEOL AL$400(400 \mathrm{MHz})$ and DRX-500 MHz spectrometer using tetramethylsilane (TMS) as an internal standard. Chemical shifts have been expressed in ppm units downfield from TMS.
- ${ }^{13} \mathrm{C}$ NMR spectra were recorded on AV-50 MHz, AV-100 MHz, JEOL AL$100(100 \mathrm{MHz})$ and DRX-125 MHz spectrometer.
- Mass spectroscopy was carried out on PI QStar Pulsar (Hybrid QuadrupoleTOF LC/MS/MS) and High-resolution mass spectra (HRMS) were recorded on a Thermo Scientific Q-Exactive, Accela 1250 pump and also EI Mass spectra were recorded on Finngan MAT-1020 spectrometer at 70 eV using a direct inlet system.
- Infrared spectra were scanned on Shimadzu IR 470 and Perkin-Elmer 683 or 1310 spectrometers with sodium chloride optics and are measured in $\mathrm{cm}^{-1}$.
- Optical rotations were measured with a JASCO DIP 370 digital polarimeter.
- All reactions are monitored by Thin Layer Chromatography (TLC) carried out on 0.25 mm E-Merck silica gel plates ( $60 \mathrm{~F}-254$ ) with UV light, $\mathrm{I}_{2}$, and anisaldehyde in ethanol as developing agents.
- All reactions were carried out under nitrogen or argon atmosphere with dry, freshly distilled solvents under anhydrous conditions unless otherwise specified. Yields refer to chromatographically and spectroscopically homogeneous materials unless otherwise stated.
- All evaporations were carried out under reduced pressure on Buchi rotary evaporator below $45^{\circ} \mathrm{C}$ unless otherwise specified.
- Silica gel (60-120), (100-200), and (230-400) mesh were used for column chromatography.

## ABSTRACT

Research Student : Yadagiri Kommagalla
Research Guide : Dr. C. V. Ramana
Title of Thesis : [Metal]-Catalyzed Carbon-Carbon and CarbonHeteroatom Bond formation: Synthesis of Biologically Active Heterocyclic Compounds

Registration Number : PGS/Ph.D./9044 dated 25.08.2011
(Title change : PGS/1228)
Date of Registration
: 01.11.2009
Place of Work
: Division of Organic Chemistry CSIR - National Chemical Laboratory, Pune (INDIA)

The thesis entitled "[Metal]-Catalyzed Carbon-Carbon and Carbon-Heteroatom Bond Formation: Synthesis of Biologically Active Heterocyclic Compounds" is divided into three chapters. The first chapter reveals the design and synthesis of two 1,4disustituted 1,2,3-triazole compounds their evaluation as anticancer agents (Section-A, Chapter 1) and as antifungal agents (Section-B, Chapter 1). The Synthesis of benzofuran conjugated sugar/nucleoside derivatives and the Synthesis of anti-inflammatory 2aroylbenzofurans via branched selective acrylate insertion are described respectively in Chapters 2 and 3.

## Chapter-I: [Cu]-Catalyzed [3+2] Azide-Alkyne Cycloaddition: Synthesis of the PIP3 antagonist PITENIN-1 analogues and their evaluation as potential anti-cancer and anti-fungal agents

PITENINS (Fig.1) are a class of small molecules which inhibit phosphoinositide 3-kinase (PI3K or PI3-kinase). PI3K plays a critical role in many cellular functions, including survival, proliferation, metabolism and motility. Hyper-activation of this pathway is known to play an important role in tumorigenesis.

PIT-II

Triazole-PITs

Figure 1: Structures of the two classes (PIT-1 and PIT-2) of inhibitors of phopshotidylinositol-3 kinase (PI3K) signaling pathway, termed PITENINs (PITs) and the newly designed $2^{\text {nd }}$ generation triazole-PITs

Considering some of the drawbacks with these PITENINS (high micromolar activity and low stability for DMPIT-I the $\mathrm{T}_{1 / 2}<2 \mathrm{~min}$ in mouse liver microsomal stability assay in vitro), the present investigations have been undertaken as means of improving the activity and pharmaceutical features of this new class of drug, have been under taken. As a first step, the possibility of replacing the susceptible thiourea unit with a 1,2,3triazole structural motif has been examined. The simple traizole derivative 1aa was prepared by the cycloaddition of alkynone $\mathbf{4 a}$ (Scheme 1) with azidophenol 5a under copper catalyzed click reaction conditions. The initial screening of 1aa against growth of A2780 human ovarian cancer cells revealed that 1aa has a comparable activity with the corresponding PIT-1 analogue.

Scheme 1: Synthesis of selected alkynol and alkynone
This initial promise has motivated us to synthesize a collection of triazole derivatives by varying the functional groups on both the aryl rings for optimization and for studing the structure activity relationship. A wide range of alkynones $\mathbf{4 b} \mathbf{- 4 e}$ have been synthesized by following the established procedure and by employing the azido phenols 5a-5e as the dipolarophiles for the Cu-catalyzed azide-alkyne [3+2]cycloaddition. Table 1 summarizes the details of the compounds synthesized and also their anticancer data. This has ultimately resulted in the identification of $\mathbf{1 e a}$ that has shown activity 20 times higher than that of the DM-PIT-1.

The activity of 1ea was further tested in lipid overlay assay, measuring binding of Akt PH domain with PIP3, spotted on micro cellulose membrane as previously described. Compound 1ea displayed substantially higher activity compared to DM-PIT-1. The inhibition of PI3K/Akt signaling in human glioblastoma U87MG and ovarian carcinoma A-2780 cells was further examined with compound 1ea. Interestingly, while a limited inhibition of Akt phosphorylation of Akt itself and several of its effectors by 1ea was observed, it displayed robust inhibition of TORC1/p70S6K/S6 pathway downstream from Akt, suggesting that the increased activity of 1ea translated into more specific inhibition of a particular pathway downstream from PI3K/Akt. Other targets of 1ea in the PI3K/Akt signaling pathway remain to be fully elucidated in the future. Finally, one of the major goals of our study was to improve the pharmacological properties of PIT-1/DM-PIT-1. The compound 1ea displayed $\mathrm{T}_{1 / 2}=119 \mathrm{~min}$ in mouse liver microsomal stability assay in
vitro (for DM-PIT-1 it was $\mathrm{T}_{1 / 2}<2 \mathrm{~min}$ ). Overall, our SAR analysis describes a new analog of PIT-1 with significantly improved anti-cancer activity and pharmacological properties.

Table 1: Variously substituted 1,2,3-triazoles synthesized and their inhibition of PIP3

${ }^{a}$ alone with compounds, ${ }^{\text {b }}$ along with TRIAL, TRIAL-tumor necrosis factor-related apoptosis-inducing ligand

Compound 1fa which is closely related to 1ea was synthesized from 3,5bis(triflouromethyl)benzoylchloride 7 by coupling with propargyl amine to procure the key intermediate $\mathbf{4 f}$, which was further subjected for the cycloaddition reaction with azidophenol 5a. The compound $\mathbf{1 f a}$ has showed good activity, but not found to be better than 1ea.

Scheme 2: Synthesis of substituted 1,2,3-triazole (1fa)

## Synthesis, characterization, antifungal evaluation and mechanistic studies of new

 1,2,3-triazole derivatives

Newly Designed 1,2,3Triazoles

Figure 2.Common sub-structural units $A-C$ found in the commercial azole-based antifungals and newly designed 1,2,3-triazole having any two of these $A$-C sub-structural units

In recent years, studies have revealed that many of the cancer drugs have the potential to be antifungal agents and conversely anti-fungal compounds also show potential anti-cancer properties. Considering this, and aided by some sub-structural elements in azole antifungal drugs two classes of 1,4-disubstituted 1,2,3-triazole compounds have been designed as potential antifungal candidates (Fig. 2).

Scheme 3 saliently describes the synthesis of some Type I precursors following simple synthetic transformations. The aromatic alkynol intermediates were synthesized by treating aryl aldehydes/ketones with ethynylmagnesium chloride and then the resulting alkynols were subjected for 1,3-dipolar cycloaddition with chloroazidophenols 5a and 5c under established conditions.

Scheme 3: Synthesis of Triazole Compounds of Type-I
The synthesis of the compounds of Type 2 started with the reaction of aryl aldehydes/ketones with propargyl bromide under Zn -mediated Barbier reaction conditions (Scheme 4). The 1,3-dipolar cycloaddition of chloroazidophenols 5a and 5c with different alkynols 9a-9g (Scheme 1B.3) was carried out under established CuAAC reaction conditions.

Scheme 4: Synthesis of Type II 1,2,3-Triazoles
These two classes of 1,2,3-triazoles were screened against C. albicans ATCC 24433, C. albicans ATCC 10231, C. glabrata NCYC 388, C. neoformans, C. neoformans ATCC 34664, A. fumigatus MCC 1046, A. niger ATCC 10578(CLSI M27-A3) and $F$. oxysporum (CLSI M38-A2). Based on the MIC results, compounds 8bc, 10cc, 10fa, 10fc, $10 \mathrm{ga}, 10 \mathrm{gc}$ and 10 da were identified as lead molecules. The mechanism of antifungal action of these compounds was investigated by different assays. Detailed experiments on the depletion of ergosterol revealed that the antifungal activity of the compounds 10ca, 10fa and 10 ga was due to lanosterol $14 \alpha$-demethylase inhibition. On the other hand, with compounds $\mathbf{8 b c}, 10 \mathbf{c c}, 10 \mathrm{fc}, 10 \mathrm{gc}, 10 \mathrm{da}$, there was no ergosterol depletion and later it has been identified that their antifungal activity was because of generation of intracellular reactive oxygen species (ROS). Compounds 10da and 10fc were most effective and showed ROS generation in $>99 \%$ cells at 2 X MIC 4X MIC concentration, respectively.

## Chapter 2: [Pd]-Catalyzed Cycloisomerization: Synthesis of benzofuran conjugated sugar/nucleoside derivatives

The modification on the sugar back bone in nucleosides is an important strategy for the development of antiviral and anticancer drugs. The sugar modifications, in particular, C-3' modified sugar unit in the nucleosides have gained significant attention for therapeutic development.

Figure 3: Strategy for benzofuran-conjugated nucleosides

Considering the widespread occurrence of the benzofuran unit in a variety of biologically active molecules, we designed the modified nucleosides having a pendant C-3'-(2-benzofuranlymethyl) unit. Figure 3 reveals our intended strategy featuring a Pdcatalyzed Sonogashira coupling cum cyclization reaction of C3'-propargyl nucleoside with $o$-iodophenol substrates. Our initial studies in this direction started with exploring the feasibility of this approach with simple sugar derived alkynols. The optimization of the Pd-catalyzed reaction was performed with xylose derived alkyne 15a and 2-idophenol (Scheme 5). The reaction was carried at rt by employing $5 \mathrm{~mol} \%$ each of $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}$ and $\mathrm{PPh}_{3}$ and CuI in a mixture of $\mathrm{Et}_{3} \mathrm{~N}$ and DMF. The reaction proceeded smoothly and the requisite benzofuran-conjugated xylose derivative 13aa was obtained in very good yield

a) $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}(5 \mathrm{~mol} \%), \mathrm{PPh}_{3}(5 \mathrm{~mol} \%), \mathrm{Cul}(5 \mathrm{~mol} \%), \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMF}, \mathrm{rt}$

Scheme 5: The synthesis of sugar- benzofuran conjugates.
Scheme 6 shows the scope of this reaction on four sugar templates $\mathbf{1 5 a} \mathbf{- 1 5 d}$ employing three representative iodophenols $\mathbf{1 4 a}-\mathbf{1 4 c}$. The reactions were facile with all the four alkynes employed and gave the corresponding sugar-benzofuran conjugates in very good yields.

Scheme 6: Scope of [Pd]-catalyzed benzofurannulation of sugar derivatives.

Having established the [Pd]-catalyzed benzofuran synthesis on simple sugar derivatives, we next focused on the feasibility of this reaction with unprotected $\mathrm{C}(3)$ propargylated nucleosides. Our initial intention was to carry out this benzofurannulation reaction on free nucleosides $\mathbf{1 5 h} \mathbf{- 1 5 j}$, thereby making a provision of substrate flexibility at the final stage and providing an easy access to synthesis of a collection of $\mathrm{C}(3)$ modified nucleosides (Scheme 7).

The synthesis of the alkynyl nucleosides $\mathbf{1 5 g} \mathbf{- 1 5 h}$ started with the selective protection of the $\mathrm{C}(5)-\mathrm{OH}$ of alkynol $\mathbf{1 5 a}$ as its pivaloate $\mathbf{1 6}$ by using pivaloyl chloride in the presence of triethylamine in dichloromethane. The hydrolysis of the acetonide group followed by peracetylation of the intermediate lactol gave an anomeric mixture of $\mathrm{C}(3)$ propargyl ribose derivatives 18 . The $N$-glycosidation of the anomeric mixture 18 was carried out under modified Vorbrüggen conditions employing thymine, and 5-flurouracil to afford the protected nucleosides $\mathbf{1 5 e} \mathbf{- 1 5 f}$, respectively. The deacetylation of $\mathbf{1 5 e} \mathbf{- 1 5 f}$ employing catalytic amounts of NaOMe in methanol gave the nucleosides $\mathbf{1 5} \mathbf{g} \mathbf{- 1 5} \mathbf{h}$ (Scheme 7) in good yields.

Scheme 7: Reagents and conditions: a) Piv-Cl, $\left.\mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 4 \mathrm{~h} ; \mathrm{b}\right) 70 \%$ ACOH, reflex 6 h ; c) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}$, DMAP, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 4 \mathrm{~h}$; d) BSA, TMSOTf, $\mathrm{CH}_{3} \mathrm{CN}, 4 \mathrm{~h}$; e) $\mathrm{NaOMe}, \mathrm{MeOH}, \mathrm{rt}, 20 \mathrm{~min}$.

Our initial experiments dealing with the Sonogashira coupling reaction of alkyne $\mathbf{1 5 g}$ (Scheme 8) were unsuccessful under the conditions described in Scheme 5 and 6. Optimization of the reaction conditions has been carried out by increasing the amounts of the copper iodide. These experiments revealed that the presence of 3 eq. of copper iodide (with respect to the alkyne) is essential. However, the isolation of pure nucleosides turned out to be a difficult proposition as the samples were always found to be contaminated with the triethylamine salts. Considering these difficulties, we next moved to the corresponding protected nucleosides $\mathbf{1 5 e - 1 5 f}$. The Sonogashira coupling of $\mathbf{1 5 e}$ with $\mathbf{1 4 a}$ proceeded smoothly in the presence of 3 equivalent of CuI and the corresponding benzofuran- nucleoside conjugate 13ea was obtained in excellent yields. The deacetylation of 13ea with NaOMe in methanol provided the desired free nucleoside 19ea.

We have utilized the optimized sonogashira coupling reaction for the synthesis of the remaining benzofuran conjugated nucleoside derivatives employing nucleoside derived alkynes with three Iodophenols (14a-14c), obtained in good yields and these were subsequently hydrolyzed with NaOMe in methanol to provide the desired free nucleoside 19ea-19fc.

Scheme 8: Raction optimization for benzofuran-conjugated nucleosides synthesis.

## Chapter 3: [Ru]-Catalyzed C-H activation: Synthesis of anti-inflammatory 2aroylbenzofurans via linear/branched selective acrylate insertion

The 2,3-disubstituted benzo[b]furan derivatives of Type 1-4 (Fig. 4) have been established as novel anti-inflammatory and/or class 3 antiarrhythmic agents. The reported procedures for the syntheses of these compounds are multistep in nature and involve harsh reaction conditions such as the Friedel-Crafts acylation and acid/base mediated condensations.

Figure 4. Categorization of medicinally important 2/3-aroylbenzo[b]furans and the structure of related drug Budiodarone

As a part of our ongoing studies on "C-H activation \& functionalization", we intended to synthesize the aroylbenzofurans of Type 2 via carbonyl directed C-H activation and alkylation with acrylates. The ruthenium-catalyzed direct addition of the ortho $\mathrm{C}-\mathrm{H}$ bonds of aryl ketones employing vinylsilanes reported by Murai et al. is one of the early examples in this area that has been subsequently expanded rapidly. However, the ruthenium-catalysed hydroarylation of acrylates has not yet been documented. Considering this, and given the industrial relevance of the products, as well as the challenging Ru-catalyzed hydroarylation of acrylates, the current exercise has been taken up.

Table 2.Catalyst screening for directed hydroarylation

| S.No | Catalyst | Yield (\%) ${ }^{\text {a }} /(\mathbf{2 2 a a} / 23 a a)$ |
| :---: | :--- | :--- |
| 1 | $\left[\mathrm{Ru}(p \text {-cymene }) \mathrm{Cl}_{2}\right]_{2}$ | $23(28 / 72)$ |

${ }^{\text {a }}$ isolated yield; $\mathrm{nd}=$ not determined $($ complex reaction mixture $)$
Initial studies using various complexes revealed that the desired alkylation of 20a is viable and, quite interestingly, branched alkylated products being formed predominantly (Table 2). The optimization experiments have been carried with $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ in order to identify to right conditions for the best branched-selective alkylation. To this end, we found that the use of $5 \mathrm{~mol} \% \mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ and $30 \mathrm{~mol} \%$ silver acetate as the additive, 3 equivalent of $\mathrm{K}_{2} \mathrm{CO}_{3}$ as base and toluene as the solvent provided the best selectivity and the yield.

Next, the compatibility of various $\alpha, \beta$-unsaturated esters as coupling partners has been examined under the optimized conditions employing 20a as the substrate (Table 3). The reactions with ethyl-, butyl-, and cyclohexyl acrylates (21b-21d) gave the corresponding products in very good isolated yields without substantial difference in the branched/linear selectivity. In case of methyl crotonate (21e), the reaction proceeded smoothly and the corresponding branched adduct 22ae was obtained as the major product and the 1,5 -addition linear adduct 24 was obtained as the minor isomer with an overall yield of $84 \%$. However, with both methyl- and butyl methacrylates (21g, 21h), the
corresponding linear adducts 23ag and 23ah were formed as the only products. In the case of ethyl cinnamate (21i), the reaction was sluggish and the branched adduct 22af was obtained as the major product in moderate yield/conversion.

Table 3: Acrylate and substrate scope

Scheme 9 provides information about the experiments conducted in order to understand the role of the directing group as well as the olefins.

Scheme 9: Scope of directing groups and olefins in branched selective alkylation ${ }^{\text {a,b }}$

${ }^{\mathrm{a}}$ Reaction conditions: $1(1 \mathrm{mmol}), 2(3 \mathrm{mmol}), \mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(5 \mathrm{~mol} \%), \mathrm{K}_{2} \mathrm{CO}_{3}(3 \mathrm{mmol})$, $\mathrm{AgOAc}(30$ mol\%); ${ }^{\text {b }}$ isolated yield and ratio determined by ${ }^{1}$ H NMR

Different C2 substituted benzofuran derivatives have been subjected for alkylation with different olefins (Scheme 3.2) under established conditions. Only in case
of 2-acetyl benzofuran did the reaction proceed smoothly, with the product formation occurring in good yield. However, the regioselectivity dropped to $\sim 1: 1$. Coming to the olefins, the coupling of $\mathbf{2 0 a}$ with styrene was facile and gave a $1: 1$ mixture. On the other hand, for the same reaction with dodec-1-ene, complete branched selectivity with partial conversion resulted.

Scheme 10. Deuterium labeling experiments with 25
Next, the deuterium labelling experiments were conducted to understand the course of the mechanism of the branched selective alkylation. As shown in Scheme 10, the deuterium incorporation was observed at the C3 position of benzofuran and also at the C2'/C6' position of the pendant aryl ring. Quite interestingly, when compound 25 was subjected for alkylation with methyl acrylate, the incorporation of deuterium at the $\beta$ position of the branched product was observed. However, the percentage of deuterium incorporation was quite nominal ( $<10 \%$ ).

Table 4. Catalyst screening for directed hydroarylation

| S.No | catalyst | $\mathrm{K}_{2} \mathrm{CO}_{3}$ | 28aa (yield \%) | 29aa (yield \%) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ | presence | no | 59 |
| 2 | $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ | absence | 75 | no |
| 3 | $\mathrm{Ru}_{3}(\mathrm{CO})_{12}$ | absence | no | 68 |
| 4 | $\left[\mathrm{Ru}(\text { p-cymene }) \mathrm{Cl}_{2}\right]_{2}$ | absence | 66 | no |

With this available information and considering the previous reports, a tentative mechanistic proposal for the branched selective alkylation has been put forward. The large steric effect of $\mathrm{PPh}_{3}$ around the metal center and the non-polar nature of the $\mathrm{Ru}-\mathrm{C}$ bond in the intermediate ruthena-cycle have been attributed as influences in the insertion
of the alkene into the $\mathrm{Ru}-\mathrm{C}$ bond taking the functional group far from the $\mathrm{PPh}_{3}$ ligands and thus leading to the branched-selective alkylation.

Considering our experiments with 2-acetylbenzofuran, where a $1: 1$ mixture of branched- and linear alkylation products were formed, to further explore in the direction of the influence of the coordinating ligand, the pyridine has been selected as a directing group. Surprisingly when 2-(2-pyridyl)-benzofuran 27a was subjected for the C-H activation and alkylation with methyl acrylate under optimized conditions, only the cross dehydrogenative adduct 29aawasformed with complete linear selectivity.

Intrigued by this, the reaction of $\mathbf{2 7 a}$ with methyl acrylate has been examined with various other complexes. Quite interestingly, with the $\left[\mathrm{Ru}(\mathrm{p} \text {-cymene }) \mathrm{Cl}_{2}\right]_{2}$ complex, the linear selective alkylation product 28aa was exclusively observed. To our surprise, the optimization experiments with the $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ complex revealed that even with this complex, when $\mathrm{K}_{2} \mathrm{CO}_{3}$ was absent, the alkylation product 28aa was obtained exclusively.

Table 5. Substrate scope for alkylation and alkynylation with acrylates

Having discovered two complementary conditions for alkylation or alkeynylation, we explored the generality of these reactions by employing a wide range of olefins and differently substituted benzofuran derivatives. The reactions with various acrylates such as ethyl-, butyl-, tert.butyl- and 4-butylcyclohexyl- acrylates (21b, 21c, 21n and 210 respectively) were compatible and gave the corresponding products in moderate to good isolated yields. However, the reactions the N -isopropylacrylamide as well as with methyl crotonatewere sluggish and the products were obtained in poor yields. Quite interestingly, with acrylonitrile ( $\mathbf{2 1 j} \mathbf{j}$, under both conditions, the alkylated 28aj and alkenylated product 29aj were obtained in a 1:1 ratio.

Coming to the mechanism, a hypothesis founded upon the more polar $\mathrm{Ru}-\mathrm{C}$ bond due to the pyridine directing group and approach of the electrophilic $\beta$-carbon close to the nucleophilic Ru-C carbon atom is provided for the exclusive linear selectivity. Coming to the role of base, after the coordinative insertion, the resulting organo-Ru intermediate can undergo either protodemetallation (by the released AcOH , in absence of base) or betaelimination (via the base-mediate hydride abstraction through the anchimeric assistance of the metal centre) to afford respectively alkylation and alkenylation products.

## CHAPTER I:

[Cu]-Catalyzed [3+ 2] Azide-Alkyne Cycloaddition: Synthesis of the PIP-3 antagonist PITENIN-1 analogues and their evaluation as potential anticancer and anti-fungal agents

## SECTION A

Synthesis of the PIP-3 antagonist PITENIN-1 analogues and their evaluation as potential anti-cancer Agents

## 1A.1.1. Over View of Cancer

Cancer is a deadly disease, which is known for uncontrolled division of cells and the ability of these cells to invade other tissues, either by direct growth into adjacent tissue through invasion or by implantation into distant sites by metastasis. ${ }^{1}$ According to the GLOBOCAN 2012 worldwide survey report, in 2012 there were 32.6 million people (over the age of 15 years) alive who were diagnosed with a cancer (2007-2012). In 2012, about 14.1 million new cancer cases have been reported and around 8.2 million cancer-related deaths. ${ }^{2}$ This was quite alarming when compared with the 2008 statistics ( 12.7 million cancer cases and 7.6 million cancer-related deaths). It was estimated that the number will increase to 19.3 million new cancer cases per year by 2025, because of the increase of the aged population. Very importantly, $56.8 \%$ of all cancers and $64.9 \%$ cancer deaths in 2012 occurred in the poor and developing countries. According to a WHO report, nearly 0.7 million Indians die of cancer every year, while over 1 million are newly diagnosed with some form of the disease. Thus, there is an urgent need for cancer control today through the development of effective and affordable drugs for less developed countries.

## 1A.1.2. Treatment

There are 200 different types of cancer diseases known till date, affecting various parts of the body which are all unique in their causes and symptoms. ${ }^{3}$ Cancer treatment is usually a combination of a number of different modalities. Most common types of cancer treatment are:

- Surgery
- Chemotherapy
- Radiation therapy
- Targeted therapy
- Antibody therapy
- Small molecule inhibitors
- Immunotherapy
- Hyperthermia
- Stem cell transplant and laser treatment

The severe side-effects caused by some of the early cancer treatment methods such as chemo-, surgery, and radiation; sometimes give a feeling that cancer treatment is worse than cancer. Once the treatment begins, people often begin to feel quite sick. Targeted therapy is another option, which has a significant impact in the treatment of
some types of cancer, and is currently a very active research area. ${ }^{4}$ For targeted therapy, which became available from the late 1990s, most conventional anticancer drugs have been designed with deoxyribonucleic acid (DNA) synthesis as their target. Most targeted therapies are either small-molecule drugs or monoclonal antibodies. ${ }^{5}$ Most monoclonal antibodies cannot penetrate the cell's plasma membrane and are directed against targets that are outside cells or on the cell surface. The past two decades has witnessed antibody-based therapy for cancer. ${ }^{6}$

Small molecule inhibitors are one of the active research areas in targeted therapy in present scenario. Small-molecule drugs are typically able to diffuse into cells and can act on targets that are found inside the cell. ${ }^{7}$ The newly introduced drugs have shifted the targets from the direct synthesis of DNA to basic function, which is responsible for tumor formation. ${ }^{8}$ One such target, the protein kinase family, has become increasingly important over the past 20 years, with approximately 30 distinct kinase enzymes being targeted by drugs under development for clinical trials. Kinases, which are part of the larger family of phosphotransferases are critical in cellular functions such as metabolism, cell signaling, protein regulation, cellular transport, secretory processes, and myriad other cellular pathways. Kinase is a type of enzyme that transfers phosphate groups from high-energy donor molecules, such as ATP, to specific substrates. The deregulation of kinase activity affects the signals that promote or regulate the cell cycle, growth factors and their receptors, signal transduction pathways and thus has emerged as a major mechanism by which cancer cells evade normal physiological constraints on growth and survival, leading to tumorigenesis. Thus, the kinase signaling pathway is an important potential target for inhibition.

Two examples of small molecule anticancer kinase inhibitors in the clinic are Gleevec (Imatinib), which is approved for the treatment of chronic myeloid leukaemia ${ }^{9}$ and gastrointestinal stromal tumours and Iressa (gefitinib) which is approved for the treatment of non-small-cell lung cancer. ${ }^{10}$ These drugs were designed to inhibit receptor tyrosine kinases that are associated with development and progression of the tumor. Targeted molecular therapies, such as, the receptor tyrosine kinase inhibitors, have shown greater tolerance than traditional non-specific chemotherapeutic drugs towards normal tissues, presenting, a larger therapeutic window.

This approach seems applicable to certain classes of intracellular signaling proteins and pathways that possess heavily mutated hotspots. Three major signaling pathways that have been identified as playing important roles in cancer include the mitogen-activated protein kinase (MAPk)/Ras, the protein kinase C (PKC) and the PI3K/AKT signaling cascade. The PI3K/AKT signaling pathway plays a vital role in the cellular functions and the deregulation or disruption of this pathway causes tumorigenesis. ${ }^{11}$

## 1A.1.3. Phosphatidylinositol 3-kinases (PI3Ks)

Phosphatidylinositol 3-kinases (PI3Ks) belong to an enzyme family of vitally important regulators for intracellular signaling pathways. PI3Ks catalyze the phosphorylation of phosphatidylinositol at the 3 '-position of the inositol ring producing secondary messenger lipids which control cellular activities including cell survival, growth and proliferation. A large proportion of cell-surface receptors, especially those linked to tyrosine kinases activate PI3Ks. ${ }^{12}$ Dysregulation of the PI3K pathway has been implicated in many human diseases. Hyper activation of this pathway is known to play an important role in tumorigenesis, whereas the deficiencies in the PI3K pathway contribute to the development of type II diabetes. Therefore, this pathway offers promising targets for the development of drugs to combat this diseases. ${ }^{13,14}$

The PI3K family is divided into three different classes: Class I, Class II, and Class III, based on their primary structure, mode of regulation, substrate specificity, tissue distribution and function within the cell. ${ }^{15,16}$ The class I PI3Ks are responsible for the production of phosphatidylinositol-3,4,5-trisphosphate (PIP3). Class I PI3Ks ( $\alpha, \beta$, and $\gamma$ ) are recruited to the plasma membrane in response to growth factor and hormone stimulation to mediate the phosphorylation of lipid phosphatidylinositol-4,5-bisphosphate (PIP2), generating PIP3, which orchestrates multiple downstream intracellular signaling events. PIP3 signaling is terminated by the phosphatase PTEN, which dephosphorylates PIP3. Genetic alterations targeting PTEN are among the most frequent mutations in human cancers, indicating a critical role of uncontrolled signaling through PIP3 in tumorigenesis and metastasis. ${ }^{17}$ This conclusion is reinforced by transgenic studies establishing that loss of PTEN leads to tumorigenesis.

Figure S1.1: The PI3K signalling pathway ${ }^{18}$

Phosphatidylinositol 4,5-bisphosphate (PIP2)

Phosphatidylinositol 3,4,5-trisphosphate (PIP3)

Figure S1.2: Phosphate transfer reaction canalized by Class I PI3K isoforms

PIP3 controls a complex cellular signaling network regulating cell growth, proliferation, and survival. The PIP3 target proteins are located in the cytosol of unstimulated cells and are recruited to the membrane through pleckstrin-homology (PH) domain-mediated binding to newly formed PIP3. Membrane translocation and activation of the PIP3 target proteins initiate a variety of local responses, including assembly of signaling complexes and priming of protein kinase cascades. ${ }^{13,14}$ PIP3 regulates an array of PH domain-containing proteins, ${ }^{19}$ such as serine-threonine kinases Akt and PDK1, GRP1, a GDP/GTP exchange factor of ADP ribosylating factor, and protein tyrosine kinases of the Bruton's tyrosine kinase (Btk) and Tec families. ${ }^{20,21}$ This diversity in PIP3 signaling makes it one of the most important second messengers downstream from growth factor and oncogene signals. A
particularly important example of PIP3-dependent activation is that of serinethreonine kinase Akt. It is achieved both through the binding of the Akt PH domain to PIP3 and membrane translocation of another target of PIP3, PDK1, which phosphorylates and activates Akt. The Akt family plays a fundamental role in cell survival, growth, and energy metabolism. ${ }^{22}$

Although lipid-protein interactions mediate PI3K signaling and are frequently deregulated in cancer, most therapeutic strategies targeting the PI3K pathway have focused on inhibitors for downstream targets, including PDK1 ${ }^{23}$ and Akt. ${ }^{24}$ Phospholipid-protein interactions have not been as actively targeted, even though lipid molecules are among the most important classes of second messengers. This is surprising considering that they represent "prototypic" small molecule-protein interactions usually involving well-defined binding sites. ${ }^{25}$ Conceptually, proteinlipid interactions may be more readily targetable compared with protein-protein interactions, which frequently involve interactions of extended flat protein surfaces difficult to disrupt by small molecules.

Figure S1.3: Small molecule antagonists of PIP3

There are many approaches focused on targeting enzymatic activities in the PI3K network. We have recently described a new approach aimed at targeting a universal central step in PI3K signal transduction, i.e. binding of PIP3 to PH domains of effector proteins. ${ }^{26}$ In particular, we have developed two selective new classes of small molecule nonphosphoinositide PIP3 inhibitors, termed PITenins (PITs), PIT-1 (N-((3-chloro-2-hydroxy-5-nitrophenyl)carbamo-thioyl)benzamide) and PIT-2 ((Z)-5-(2-benzyl-5-hydroxy-4-nitrobenzylidene)-2-thioxothiazolidin-4-one,). ${ }^{27,28}$
Surprisingly, these two structurally dissimilar molecules displayed very similar anti tumor activities, including induction of apoptosis and metabolic stress and inhibition of cell migration and invasion. Particularly, both PIT-1 and PIT-2 displayed
synergistic toxicity with TRAIL in human glioblastoma U87MG cells. These activities have been linked to the inhibition of Akt signaling and actin remodeling by ARF6, two pathways regulated by PI3K. These in vitro activities of PITs translated into the significant inhibition of tumor growth and lung metastasis formation in 4T1 and B16-F10 syngeneic xenograft models by the dimethyl analogue of PIT-1.

Despite the promising initial results, PITs have displayed some obvious limitations, including high micromolar activity, this means, that the particular compound required more quantity and as well as multiple non-drug-like features. In particular, nitrophenyl and thiourea moieties of PIT-1 described potential toxicity concerns and metabolic liabilities. The initial analysis of the PIT-1 series revealed surprisingly specific SAR for a micromolar compound suggesting several changes to the molecule, leading to some increase in activity and changes in targeting different PH domains. In particular, the addition of two methyl groups to the phenyl ring in PIT-1 (DM-PIT-1, Fig. S1.3) resulted in some increase in activity and improved incorporation into long-circulating PEG-PE micelles for in vivo delivery. ${ }^{27,29}$ DM-PIT-1 displayed $\mathrm{T}_{1 / 2}<2 \mathrm{~min}$ in mouse liver microsomal stability assay in vitro. Furthermore, changes to the nitrophenyl ring were identified. However, these results did not address the main limitations of the PIT-1 series. Due to these limitations, the present inventions were undertaken to explore and seek to improve activity and pharmaceutical features of this new class of anti-cancer lead molecule. Our first concern was to replace the susceptible thiourea unit with a stable bioisostere and the nitro $\left(\mathrm{NO}_{2}\right)$ group with different functional groups.

## 1A.1.4. Bioisossters

Over the years, the medicinal research mainly focused on the development of a clinically useful drug, providing either a cure for a particular disease or symptomatic relief from a physiological disorder. Sometimes the lead compound with a desired pharmacological activity may have associated with it undesirable side effects, characteristics that limit its bioavailability, or structural features which adversely influence its metabolism and excretion from the body. ${ }^{30}$ There is a strong necessity to overcome from these issues. ${ }^{31}$ The medicinal chemists successfully demonstrated the alternative approach such as 'Bioisosterism' after Friedman introduced this concept in 1951 for the rational modification of lead compounds into safer and more clinically
effective agents. ${ }^{32}$ This concept was well exploited for drug development by using atoms and small molecules as bioisosters. ${ }^{33}$

The hetero cycle molecular units are found to be prominent bioisosters. ${ }^{32,33}$ In recent years the 1,2,3-triazole units have attracted major attention for bioisosteric replacement. The 1,2,3-triazole units have been well explored as bioequivalent surrogates for the amide bond, ${ }^{34}$ due to the structural similarities, including: a) three nitrogens of triazole mimicking the carbonyl group of amide, b) the C-H bond of triazoles as hydrogen bond donors similar to the $\mathrm{N}-\mathrm{H}$ bond of amide and as electrophilic and c) the polarized two carbons of triazole are electronically similar to the carbonyl carbon of amide. ${ }^{35}$

Figure S1.4: Structural comparison of amide and 1,2,3-triazole
Besides the potential bioisosteric replacement of amide bond in peptides, triazoles have also been predicted that they might act as bioisosteres of the acylphosphate ${ }^{36}$ and trans-olefinic moieties. The phosphate unit has replaced by 1,2,3triazole in the search of inhibitors of enzymes. ${ }^{36}$ The substitution of a trans-olefinic group with a triazole in resveratrol proved to be more rewarding. This idea was supported by molecular modeling calculations (MM2) that suggested that this modification did not alter the spatial positioning of the phenolic hydroxyls that determine the biological activity of this phytoalexin. The effective trans-olefinic/1,4disubstituted triazole replacement is not limited to resveratrol, ${ }^{37}$ as it was possible to maintain estrogenic activity in diethylstilbestrol analogueues. ${ }^{38}$

Grimm's bioisosteric rule would suggest that obvious candidates for bioisosteric substitution with triazoles should be five-membered rings containing two nitrogen atoms. Some of the 1,4 regioisomers, but not their 1,5 counterparts, were more potent competitive inhibitors compared to fipronil. The potency and selectivity
were determined by substituents, strengthening the idea that triazole is a Grimm's bioisostere of pyrazole (Fig. S1.5). ${ }^{39}$ This claim is reinforced by experiments on carbocyclic nucleosides. The adenine has been replaced with several heterocyclic moieties, with the 1,4 -disubstituted triazole derivative showing the most potent antiviral activity against the vaccinia virus among the five-membered rings tested (Fig. S1.5). ${ }^{40}$

Figure S1.5: Some examples on triazole unit used as potential bioisoster

## 1A.1.5. Synthesis of 1,2,3-triazole

The $1,2,3$-triazoles have been were well known since the early $20^{\text {th }}$ century. Dimroth discovered the formation of triazoles by the addition of organic azides to acetylenes. ${ }^{41}$ Later, Alder and Stein described in 1931, the reaction of phenylazide with bicyclo-[2,2,1] hept-2-ene and its derivatives, producing the 1,2,3-triazole. ${ }^{42}$ However, the synthesis of 1,2,3-triazoles has required harsh and laborious reaction methods. In 1961, Rolf Huisgen has introduced the [3+2] cycloaddition between a
terminal alkyne and an azide to generate substituted 1,2,3-triazoles as a mixture of the 1,4 -adduct and the 1,5 -adduct at $98{ }^{\circ} \mathrm{C}$ in 18 hours (Scheme S1.1). ${ }^{43}$ The regiomeric mixture of this reaction outcome was a major disadvantage. However, in the beginning of the last decade, the seminal reports by Meldal and Sharpless has introduced a highly 1,4-regioselective version and, more importantly, conducted the reaction at rt by employing the copper-catalyst and have initiated the understanding the scope of this organic reaction. ${ }^{44,45}$ Sharpless has referred to this cycloaddition as "the cream of the crop" of click chemistry and "the premier example of a click reaction." Later the metal catalyzed version of this reaction has been well explored.

Scheme S1.1: Classical Huisgen's 1,3 dipolar addition

## 1A.1.5.1. Copper Catalysis

In 2002, two chemists, Sharpless and Meldal independently reported the metal catalyzed version of Huisgen's azide-alkyne cycloaddition. ${ }^{44,}{ }^{45}$ The seminal contribution of Sharpless and coworkers was later referred to as the "Click Chemistry" concept (Scheme S1.2). This copper(I) catalyzed variant of the Huisgen 1,3-dipolar cycloaddition is a noteworthy example in that it is no longer a true concerted cycloaddition, in which organic azides and terminal alkynes are united to afford 1,4-disubstitueted 1,2,3-triazoles as sole products. Later, this reaction was termed the copper(I)-catalyzed Azide-Alkyne Cycloaddition (CuAAC). In the presence of a base, the terminal hydrogen, being the most acidic is deprotonated first to give a Cu acetylide intermediate, after which the azide displaces another ligand and binds to the copper. Then, an unusual six-membered copper(III) metallacycle is formed. Ring contraction to a triazolyl-copper derivative is followed by protonolysis that which delivers the triazole product and closes the catalytic cycle.

Scheme S1.2: Copper variation of 1,3 dipolar cycloaddition reaction of azide and alkyne (Click Reaction)

## 1A.1.5.2. Ruthenium Catalysis

The ruthenium-catalysed 1,3-dipolar azide-alkyne cycloaddition (RuAAC) gives the 1,5 -triazole. ${ }^{46}$ Unlike CuAAC in which only terminal alkynes react, in RuAAC, both terminal and internal alkynes can participate in the reaction (Scheme S1.3). This suggests that ruthenium acetylides are not involved in the catalytic cycle. The proposed mechanism suggests that in the first step, the spectator ligands undergo the displacement reaction to produce an activated complex which is converted, via oxidative coupling of an alkyne and an azide to the ruthenium containing metallacycle (Ruthenacycle). The new C-N bond is formed between the more electronegative and less sterically demanding carbon of the alkyne and the terminal nitrogen of the azide. The metallacycle intermediate then undergoes reductive elimination releasing the aromatic triazole product and regenerating the catalyst or the activated complex for further reaction cycles. $\mathrm{Cp}{ }^{*} \mathrm{RuCl}\left(\mathrm{PPh}_{3}\right)_{2}, \mathrm{Cp}^{*} \mathrm{Ru}(\mathrm{COD})$ and $\mathrm{Cp}^{*}\left[\mathrm{RuCl}_{4}\right]$ are commonly used ruthenium catalysts. Catalysts containing the cyclopentadienyl $(\mathrm{Cp})$ group are also employed. However, better results are observed with the
pentamethylcyclopentadienyl $\left(\mathrm{Cp}^{*}\right)$ version. This may be due to the sterically demanding $\mathrm{Cp}^{*}$ group which facilitates the displacement of the spectator ligands. ${ }^{47}$

Scheme S1.3: Ruthenium catalyzed of 1,3 dipolar cycloaddition reaction of azide and alkyne

## 1A.1.5.3. Silver Catalysis

Recently, the discovery of a general $\mathrm{Ag}(\mathrm{I})$-catalyzed azide-alkyne cycloaddition reaction (Ag-AAC) leading to 1,4-triazoles has been reported. ${ }^{53}$ The mechanistic features are similar to the generally accepted mechanism of the copper(I)catalyzed process.

Scheme S1.4: Ag(I)-catalyzed azide-alkyne cycloaddition reaction
Interestingly, silver(I)-salts alone are not sufficient to promote the cycloaddition. However the ligated $\operatorname{Ag}(\mathrm{I})$ source has proven to be exceptional for the AgAAC reaction. Curiously, pre-formed silver acetylides do not react with azides; however, silver acetylides do react with azides under catalysis with copper(I). ${ }^{48}$

## 1A.1.6. Click Chemistry Overview

Click chemistry is a modular synthetic approach towards the assembly of new molecular entities and has recently emerged to become one of the most powerful tools in drug discovery, chemical biology, and proteomic applications. ${ }^{50}$ The wide scope of CuAAC is firmly demonstrated by its use in different areas of life and material sciences such as drug discovery, ${ }^{51}$ bioconjugation, ${ }^{52}$ polymer and materials science ${ }^{53}$ and related areas including supramolecular chemistry. DNA labeling and oligonucleotide synthesis, the assembly of glycoclusters and glycodendrimers, ${ }^{54}$ the preparation of stationary phases for HPLC column, the development of microcontact printing, the conjugation of molecular cargos to the head group of phospholipids, ${ }^{55}$ and the construction of bolaamphiphilic structures are further examples of the use of CuAAC.

## 1A.1.6.1. Click Chemistry in Drug Discovery

Current drug discovery relies on massive screening of chemical libraries against various extracellular and intracellular molecular targets to find novel chemotypes with the desired mode of action. Click chemistry simplifies compound synthesis, enabling faster lead discovery and optimization. ${ }^{55,56}$ Click chemistry-based drug discovery mainly falls into three types: (1) high-throughput screening, (2) fragment-based drug discovery, and (3) dynamic template-assisted strategies in fragment-based drug discovery. In recent years, high-throughput technologies have gained the attention of pharmaceutical and biotechnology companies for lead drug discovery leads and it is now also being used for basic and applied research in academia. It comprises the screening of large chemical libraries for activity against biological targets via the use of automation, miniaturized assays, and large-scale data analysis.

The copper catalyzed click reaction has several applications in the drug discovery of enzyme inhibitors. The malfunctioning of PTP1B (protein tyrosine phosphatase 1B) leads to various human diseases like cancer, diabetes, obesity, and inflammation. Zhang and co-workers prepared a highly potent and selective mPTPB inhibitor (S1.1, Fig. S1.6 ) using a novel, double click chemistry strategy. ${ }^{57}$ Later Xie et al. also reported new PTP inhibitor entities. Triazolyl glucosyl, galactosyl, and mannosyl serine and threonine derivatives were efficiently synthesized via the click
reaction, one of which (compound S1.1, Fig. S1.6) was identified as a potent and selective PTP1B inhibitor against a panel of homologous PTPs with $\mathrm{IC}_{50}=$ $5.9 \pm 0.4 \mu \mathrm{M} .{ }^{58}$ Zhou and co-workers recently reported a potent and selective mPTPB inhibitor (S1.2 and S1.3, Fig. S1.6) with highly efficacious cellular activity, from a combinatorial library of bidentate benzofuran salicylic acid derivatives assembled by click chemistry. ${ }^{59}$

Figure S1.6: Biologically active compounds via click chemistry
Kumar and co-workers have recently reported the synthesis of 3-phenylpyrazolopyrimidine-1,2,3-triazole conjugates using the click chemistry approach and revealed that they displayed promising Protein Kinase inhibition. The hexyl triazolyl-substituted 3-phenylpyrazolopyrimidine (S1.4, Fig. S1.6) exhibited potent inhibition of the SRC kinase with an $\mathrm{IC}_{50}$ value of $5.6 \mu \mathrm{M}$. Canonico et al. successfully constructed a small library of triazole analogueues of antitumoral drug FK866 using click chemistry techniques. Among the synthesized triazole analogueues, compound S1.5 (Fig. S1.6) displayed nanomolar potency against depletion of NAD levels. Xie and co-workers also employed click chemistry for the synthesis of novel nucleoside conjugates between uridine and N -acetylglucosamine or oleanolic acid derivatives. Compund S1.6 (Fig. S1.6) showed good inhibitory activity against glycogen phosphorylase with $\mathrm{IC}_{50}=13.6 \mu \mathrm{M}$. Cravatt et al. recently
developed the triazole urea inhibitors S1.7and S1.8 (Fig. S1.6), which were highly potent inhibitors against their respective serine hydrolase targets in mouse T -cell proteomes. Mohapatra and co-workers reported one-pot synthesis of novel tetracyclic scaffolds that incorporate a fusion of a proline, 1,2,3-triazole ring with [1,4]-benzodiazepin-8(4H)-one ring systems following click chemistry. Compound S1.9 (Fig. S1.6) has showed good serine protease inhibition activity with $\mathrm{IC}_{50}=108.2 \mu \mathrm{M}$. Danishefsky et al. employed click chemistry for the synthesis of novel heat shock protein 90 (Hsp90)-based anticancer agent, triazole-cycloproparadicicol derivative, S1.10 (Fig. S1.6). Among the best-known examples of triazole-containing structures is tazobactam, a $\beta$-lactamase inhibitor that is marketed in combination with the broad spectrum antibiotic piperacillin. Tazobactam (S1.11) and related triazole-containing compounds ( $\mathbf{S 1 . 1 2}$ and S1.13; Fig. S1.5) turned out to be potent $\beta$-lactamase inhibitors with higher potency than clavulanic acid and sulbactam, and the triazole ring appears to play a pivotal role its potency. ${ }^{50}$

## 1A.2. Present Work:

The aim of the present work was to optimize the anti cancer activity of the initially identified structural scaffold of the PIT1, and to explore the SAR analysis. In this scenario, our first concern was to replace the susceptible thiourea unit with a stable bioisostere and the nitro $\left(\mathrm{NO}_{2}\right)$ group with different functional groups. The 1,2,3-triazole structural motif has attracted our attention to as a replacement for the thiourea unit. ${ }^{32,}{ }^{33}$ While 1,2,3-triazoles are not present in naturally occurring compounds, the triazole unit has been identified as the bioequivalent surrogate for the amide bond. ${ }^{40}$ This concept has been well exploited for the development of potential anticancer agents as well as for developing non-nucleoside reverse transcriptase inhibitors. We are anticipating the best anti tumor activity with the 1,4 -disubstituted-1,2,3-triazole derivatives (Triazole-PITs). These Triazole-PITs have been designed as the structural mimics of DM-PIT-1 and as potential second-generation PITenins (PITs) as shown in Figure 1.1. The triazole unit was divided into three rings for a better understanding of the synthetic strategy and SAR analysis. As shown below, this led us to identify two structural units for the synthesis of - i. alkynone; ii. substituted $o$-azidophenol.

Figure 1.1: Anticipated potential second-generation PITenins

## 1A.2.1. Chemistry

## 1A.2.1.1. Synthesis of Alkynone (4a-4e)

A total of five different alkynones ( $\mathbf{4 a - 4 e}$ ) having different substituted on the benzene ring or having a naphthalene unit have been designed in this context. Scheme 1.1 reveals the general approach that has been followed for their synthesis. For example, the synthesis of alkynone $\mathbf{4 a}$ started with the addition of ethenyl magnesium chloride in THF to commercially available benzaldehyde in order to furnish the alkynol 3a in good yield. ${ }^{60}$ The compound was confirmed by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and IR spectroscopic techniques. In the ${ }^{1} \mathrm{H}$ NMR of the compound 3a, the acetylenic proton
appeared at $\delta 2.26 \mathrm{ppm}$ as a doublet with $J=2.3 \mathrm{~Hz}$ and the benzylic proton resonated at $\delta 5.43 \mathrm{ppm}$ as a singlet. The presence of acetylenic group was also evident from the IR spectrum, where the absorption was observed at $3307 \mathrm{~cm}^{-1}$. The compound 3a was subjected for oxidation with IBX (in EtOAc, reflux for 2 h ) ${ }^{61}$ on order to procure the alkynone $\mathbf{4 a}$ in excellent yield. The structure of the compound $\mathbf{4 a}$ has confirmed by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR. In the ${ }^{1} \mathrm{H} \mathrm{nmr}$ spectrum of compound $\mathbf{4 a}$, the benzylic CH has disappeared and in the ${ }^{13} \mathrm{C}$ spectrum, the carbonyl carbon has appeared as a singlet at $\delta 196.4 \mathrm{ppm}$.

Scheme 1.1: Synthesis of selected alkynone

## 1A.2.1.2. Synthesis of 4-chloroazidophenol

The 4-chloroazidophenol was prepared from commercially available 2 -amino, 4-chlorophenol by a sequence of diazotization followed by azide substitution, affording the compound $\mathbf{5}$ with good yield (Scheme 1.2). ${ }^{62}$

Scheme 1.2: Synthesis of selected azidophenols

## 1A.2.1.3. Synthesis of 1,4-substituted 1,2,3-triazole (1aa)

The resulting alkynone $4 \mathbf{a}$ was subjected for the cycloaddition with 4chloroazidophenol $\mathbf{5 a}$ by using the well established copper catalyzed click reaction conditions. One equivalent of alkynone $\mathbf{4 a}$ and one equivalent of 4 -chloroazidophenol $5 \mathbf{a}$ were dissolved in tert- $\mathrm{BuOH} /$ water (3:1) and the resulting solution was treated with $20 \mathrm{~mol} \% \mathrm{CuSO}_{4} .5 \mathrm{H}_{2} \mathrm{O}$ and $20 \mathrm{~mol} \%$ sodium ascorbate. The reaction mixture was stirred at room temperature ( $0.5-1 \mathrm{~h}$ ) for completion of cycloaddition to deliver the requisite 1,2,3-triazole 1aa (Scheme 1.3). ${ }^{63}$ The constitution of compound 1aa was confirmed with the help of ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and HRMS data. For example, in the ${ }^{1} \mathrm{H}$ NMR spectra of the compound 1aa, the characteristic traizole-C-H resonated at $\delta$ 9.07 ppm as a singlet. In the ${ }^{13} \mathrm{C}$ NMR spectra, the carbonyl carbon appeared at $\delta$ 184.7 ppm (see the experimental section). In the HRMS, the exact mass of the compound showed, as calculated, for $\mathrm{C}_{15} \mathrm{H}_{10} \mathrm{O}_{2} \mathrm{~N}_{3} \mathrm{ClNa}[\mathrm{M}+\mathrm{Na}]^{+}: 322.0354$ and it was found to be 322.0357 . The initial screening of 1aa against the growth of U87MG human glioblastoma cells revealed that 1aa has a comparable activity with the corresponding PIT-1 analogueue. The compound 1aa alone depicted $\mathrm{EC}_{50}$ value 103.6 $\mu \mathrm{M}$ and, with the combination of TRIAL depicted the $\mathrm{EC}_{50}$ value with further improvement such as $51.6 \mu \mathrm{M}$ (table-1.1).

Scheme 1.3: Synthesis of 1,4-disubstituted 1,2,3-triazole (1aa)

## 1A.2.1.4 Synthesis and SAR analysis of designed 1,4-disubstituted 1,2,3-triazoles

This initial promising result has motivated us to synthesize a collection of triazole derivatives by varying the functional groups; the basic skeleton of the triazole has been divided into three rings $\mathrm{A}, \mathrm{B}$ and C , for the convenience of indication. We have synthesized three 1,2,3-triazoles such as $\mathbf{1 a b}, \mathbf{1 a c}$ and 1ae (Fig. 1.2), then tested in U87MG human glioblastoma cells (the antitumor activity has been shown in the table 1.1). The compound 1 ac showed some improved activity as $\mathrm{EC}_{50} 48.9 \mu \mathrm{M}$ alone and $42.3 \mu \mathrm{M}$ with combination of TRIAL by changing the position of the chloro
group and, interestingly, with the replacement of position and functional group with the methyl group, compound 1ae produced the better activity (entry 6, table 1.1). However 1ab doesn't show any significant activity in U87MG cells. These results indicated that the nature and position of the substituent or functional group has an important role in the tumor suppression activity.

$E C_{50}=>100 \mu \mathrm{M}$ alone $=>100 \mu \mathrm{M}$ with TRIAL

$\mathrm{EC}_{50}=48.9 \mu \mathrm{M}$ alone $=42.3 \mu \mathrm{M}$ with TRIAL

$\mathrm{EC}_{50}=8.1 \mu \mathrm{M}$ alone
$=8.0 \mu \mathrm{M}$ with TRIAL

Figure 1.2: Selected variously substituted triazoles
To pursue the phenolic hydroxyl group and orientation of triazole ring influence on the tumor growth, we have protected the hydroxyl group 4chloroazidophenol $\mathbf{5 a}$ as its methoxy ether $\mathbf{5 f}$. Compound $\mathbf{5 f}$ has been subjected for the $\mathrm{CuSO}_{4}$ catalyzed click reaction with alkynone $\mathbf{4 a}$ under the conditions as used in the synthesis of 1aa-1ad. Surprisingly, the regiomeric mixture of 1,4-disubstituted (1af) and 1,5-disubstituted triazole (1af') adducts were observed. The compounds were confirmed by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and HRMS. However, these molecules have not showed any impressive results and again lacked activity in A2780 cells. These results suggested that the orientation of the triazole ring and the phenol hydroxy group is essential for activity.

Scheme 1.4: Synthesis of phenol hydroxyl protected1,2,3-triazole regiomers

Next, we pursued modification of the substituents on the phenyl ring A. A wide range of alkynones $\mathbf{4 b}-\mathbf{4} \mathbf{e}$ have been synthesized by following the established procedure (Scheme 1.1) and the azido phenols 5a-5e (Scheme 1.2) have been used as the dipolarophiles for the Cu-catalyzed azide-alkyne [3+2]-cycloaddition. All the new
compounds have been characterized completely with the help of spectral and analytical data.

In this course of SAR studies, the compounds $\mathbf{1 b a}, \mathbf{1 b b}, \mathbf{1 b c}, \mathbf{1 b d}$ and $\mathbf{1 b e}$ having dimethyl groups on the ring A and differing in the functional groups on the ring C have been synthesized and were taken forward for screening against human ovarian cancer cells. However, structurally modified DM-PIT-1 analogueues have shown only limited cellular activity (Fig. 1.3 and Table 1.1).

Figure 1.3: Selected variously substituted triazoles
Next, 1ca, 1cb, and 1ce having a $p$-isopropyl group on the ring A and differing in the functional groups on the ring C , have been synthesized. The screening of these compounds against human ovarian cancer cells revealed that only, the chloro substituted compound 1ca has shown moderate activity, while other compounds were ineffective (Fig. 1.4 and Table 1.1).

Figure 1.4: Selected variously substituted triazoles
Next, the replacement of the aryl ring A with a napthyl has also been examined. Compounds $\mathbf{1 d a}, \mathbf{1 d b}$ and $\mathbf{1 d e}$ having the naphthyl unit in place of the ring A have been synthesized and screened. However, there was no improvement in the activity (Figure 1.5 and Table 1.1).

Figure 1.5: Selected variously substituted triazoles
Next, we intended to incorporate the $\mathrm{CF}_{3}$ group in the triazole unit. Very interestingly, all the endeavors indicated that the addition of the $\mathrm{CF}_{3}$ group at the $\mathrm{C}-3$ and C-5 positions on ring A in combination with a chloro group at C-4 position of the ring C (YK-NCL-240, 1ea) showed excellent improvement (17 times higher than that of the DM-PIT-1 in anti-tumor activity.

$E C_{50}=11.99 \mu \mathrm{M}$ alone
$=3.15 \mu \mathrm{M}$ with TRIAL

Scheme 1.5: Synthesis of 1,4-disubstituted 1,2,3-triazole (1ea)
Next, we have synthesized $\mathbf{1 f a}$ which contained an amide moiety of DM-PIT1, but otherwise resembled 1ea. The compound $\mathbf{1 f a}$ was synthesized from 3, 5bis(triflouromethyl)benzoyl chloride 7 by nucleophilic displacement with propargyl amine to procure the key intermediate $\mathbf{4 f}{ }^{70}$ which was further subjected for the cycloaddition reaction with 4-chloro, 2-azidophenol 5a (Scheme 1.6). The compound $\mathbf{1 f a}$ has showed good activity, but the activity was seen to be lower than that of 1ea.

Scheme 1.6: Synthesis of substituted 1,2,3-triazole (1fa)

## 1A.2.3. Chemistry

${ }^{\text {a }}$ compounds were tested in U87MG human glioblastoma Cells and ${ }^{\text {b }}$ tested in A2780 human ovarian cancer Cells

Based on the preliminary experiments and SAR analysis, the results indicated that the compound 1ea showed better activity among all the triazole analogueues that were tested. The compound 1ea has been selected for further progress in the direction of examining its pharmacological properties. The in vitro and in vivo studies with compound 1ea have been carried by Alexei's group at Tufts University. Following are some important features need to highlight!

1. The lipid overlay assay (measuring the binding of the Akt PH domain with $\mathrm{PI}(3,4) \mathrm{P} 2$, spotted on microcellulose membrane) revealed that $\mathbf{1}$ ea displayed substantially higher activity compared to PIT-1.
2. The studies on the inhibition of PI3K/Akt signaling in human glioblastoma U87MG and ovarian carcinoma A-2780 cells suggested that increased activity of 1ea might be due to more specific inhibition of a particular pathway downstream from PI3K/Akt.
3. In vitro cell viability studies with A2780 human ovarian cancer cells indicated that the $\mathrm{EC}_{50}$ value for $\mathbf{1}$ ea was improved to 15 -fold over DM-PIT1 and that was 17 -fold in combination with TRAIL. A similar trend was observed with the other human cancer cell lines: U87MG human glioblastoma cells, T47D human breast cancer cells, and DU145 human prostate cancer cells.
4. In addition to activation of cell death, PITs displayed several additional important properties. First, it was found that PIT-1 analogueues reverse resistance of cancer cells to anti-cancer cytokine TRAIL. This led to synergistic cytotoxicity of PIT-1 and TRAIL when applied in combination. This useful property was retained with 1ea.
5. In Vitro inhibition of cellular migration by using wound healing assay model with T47D, U87MG, and DU145 cells revealed that 1ea has not only increased cell death, but also suppressed cell migration and invasion though the attenuation of actin cytoskeleton remodeling.
6. In Vivo tumor inhibition studies in mice models by 1ea revealed thatthe administration of the combination of TRAIL and $\mathbf{1}$ ea resulted in significantly reduced tumor weight. These formulations were also found to be well tolerated in mice, as there was no apparent toxicity or loss of body weight.
7. Finally, for compound 1ea, the $\mathrm{T}_{1 / 2}=119 \mathrm{~min}\left(\mathrm{CL}=19.4 \mu \mathrm{~L} * \mathrm{~min}^{-1} * \mathrm{mg}^{-1}\right)$ was determined through the mouse liver microsomal stability assay. In the same assay DM-PIT- 1 displayed $\mathrm{T}_{1 / 2}=1.8 \mathrm{~min}\left(\mathrm{CL}=1262 \mu \mathrm{~L} * \mathrm{~min}^{-1} * \mathrm{mg}^{-1}\right)$.
8. Pharmacokinetics analysis following intravenous injection of $1 \mathrm{mg} / \mathrm{kg}$ of the drug showed reasonable $\mathrm{T}_{1 / 2}=3.22 \mathrm{hr}$ with a CL of $930 \mathrm{~mL} / \mathrm{hr} / \mathrm{kg}$ and a bioavailability of $85.1 \%$ following intraperitoneal administration.

Overall, our SAR analysis describes a new analogue of PIT-1 with significantly improved anti-cancer activity and pharmacological properties, which may present a promising molecule for further analysis in mouse xenograft models.

General experimental procedure: To a solution of azide 5 (1.0 eq.) and alkyne 4 (1.1 eq.) in ${ }^{\mathrm{t}} \mathrm{BuOH}: \mathrm{H}_{2} \mathrm{O}$ (3:1) at rt , sodium ascorbate ( 0.2 eq.) and $\mathrm{CuSO}_{4} .5 \mathrm{H}_{2} \mathrm{O}$ ( 0.2 eq.) were added and the resulting brick reddish mixture was stirred vigorously for 30 min. The reaction mixture was diluted and extracted with EtOAc. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvents were evaporated under reduced pressure. The product was purified by column chromatography.

## SECTION B

Synthesis, characterization, antifungal evaluation and mechanistic studies of new 1,2,3 triazole derivatives

## 1B.1. Introduction

## 1B.1.1. History of Fungal diseases

Fungal infections constitute an ever-growing medical problem causing an enormous economical burden for healthcare with high annual costs exceeding billions not only in India but also in the western world. ${ }^{63}$ In developing countries like India, high costs associated with nosocomial infectious diseases often preclude efficient therapies. The major fungi infecting humans include Candida spp (C. albicans, glabrata and especially parapsilosis in India) accounting for $75 \%$ of all infections and representing the fourth leading cause of nosocomial diseases. Further, filamentous Aspergillus spp (i.e. A. fumigatus) or the yeast Cryptococcus neoformans and rare emerging fungal pathogens cause up to $25 \%$ of disseminated fungal infections. In the developing world, there are $\sim 1$ million new cases of cryptococcal disease reported per year resulting in 675000 deaths. ${ }^{64}$ The mortality of about $40 \%$ just for candidemias exceeds that of all Gram-negative bacterial septicemias, emphasizing the medical importance of fungal diseases. Life threatening systemic fungemias develops in patients with severely impaired immunity (organ/bone marrow transplants, AIDS, cancer, neonates, and intensive care unit patients). The high mortalities are to a significant extent owing to inaccurate diagnostics, but also because current therapies rely upon a limited spectrum of high cost drugs. Hence, invasive fungal diseases are serious medical conditions, demanding a permanent attention in basic and clinical research, but also in translational antifungal drug discovery. ${ }^{65}$

The term mycosis refers to conditions in which fungi invade the resistance barriers of the human body and establish infections. There are approximately 1.5 million different species of fungi on Earth, but only about 300 of those are known to cause infection. ${ }^{66}$ These mycoses are of different types. Infections can be superficial that is situated at or close to the surface of the skin, or systemic, which means they can affect the body as a whole rather than individual parts or organs. Fungal infections are divided in the following groups ${ }^{66}$

1. Superfical mycoses
2. Cutaneous mycoses
3. Subcutaneous mycoses
4. Systemic mycoses due to primary pathogens
5. Systemic mycoses due to opportunistic pathogens

The fungal pathogens are divided majorly into two classes - i. primary true pathogens (Histoplasma capsulatum, Blastomyces dermatitidis and Coccidioides immitis), and ii. opportunistic pathogens. Increase in the population of immunocompromised patients and increase in resistance against currently used drugs led to changing epidemiology and the emergence of fungal pathogens which were previously considered clinically insignificant. Most infections are caused by Candida albicans and Aspergillus sp. (A. fumigatus and A. flavus). ${ }^{67}$ However in the last 2-3 decades, their percent share has declined due to emergence of pathogenic fungi which include - Acremonium sp., Acremonium terreus, non-albicans Candida sp. (C. glabrata, C. parapsilosis, C. krusei), Cryptococcus neoformans, Fusarium sp., Microsporum sp., Paecilomyces sp., Penicillium marneffei, Rhizopus oryzae, Trichoderma sp., Trichophyton sp., Trichosporon sp. etc.

Over the past two decades, fungal infections have increased significantly in frequency and have become the major reason for morbidity and mortality. ${ }^{68}$ As advances in medical care have improved is has the survival of patients with severe and life-threatening illnesses. The more aggressive nature of such care has led to a rapid increase in the number of immunosuppressed population which includes the patients with AIDS, autoimmune diseases, burns, radiotherapy, chemotherapy and transplantation. These changes have been correlated with a substantial increase in the rate of invasive fungal infections (IFIs). Apart from the increased number of immunocompromised hosts, the limited repertoire of antifungal drugs and resistance development against current anti-fungal drugs has aggravated the situation. ${ }^{69}$

## 1B.1.2. History of antifungal agents

In disparity to the steep rise in the number of fungal infection cases, only a few drugs have been developed over the past 5-6 decades (Fig. S1.7). Currently, five classes of compounds are used clinically to treat systemic mycoses. Just after the Second World War the treatments available for fungal infections were weak acids and phenolic dyes. In the early 1950s the available systemic antifungal drugs were nystatin and amphotericin B, but toxicity limited their use. ${ }^{70}$ In the early 1960's

Griseofulvin, the first orally effective antibiotic was used for dermatophytosis management and later broad-spectrum agents arrived, with the first being iodinated trichlorophenol haloprogin, which functioned by disrupting the fungal cell membrane. After two decades without any progress, the field of medical mycology was revolutionized by the development of the azole antifungal agents. Imidazole agents such as clotrimazole, miconazole, sulconazole and bifonazole acted by binding to cytochrome p-450, thus blocking ergosterol synthesis in the fungal cell membrane. ${ }^{71}$ However, the azole group of drugs is known to have caused anaphylaxis like side effects. This caused the scientific community to look for new drugs.

Figure S1.6: Triazole-based antifungal agents

The long haul was accounted with for the development of triazole antifungal agents that were less likely to cause hepatotoxicity, possibly due to their diminutive effects on cytochrome p-450-dependent enzymes. Terconazole was the first triazole developed, followed by itraconazole and then fluconazole. Fluconazole was marketed as Diflucan in the US and UK and over 30 countries worldwide. The new millennium brought echinocandins to the markets, which are the newest class of antifungals. ${ }^{70}$ They are characterized by their inhibition of the synthesis of ( 1,3 )- $\beta$-D-glucan (a key component of many fungal cell walls) and are therefore the first class of antifungal agents that act against a specific component of the fungal organisms and not
mammalian cells. Then second generation 1,2,4-triazoles, Voriconazole in 2002 and Posaconazole in 2005 (Fig. S1.6), were later introduced in the market. Very recently, Ravuconazole has invented new drugs beginning from tertiary alcohol, which is currently undergoing phase II clinical trials. It is highly active against a wide range of fungi. ${ }^{72}$ The timeline for the development of antifungal agents is shown in Figure S1.7.

Figure S1.7. Progress of antifungal drugs development (Compiled from - Lewis, 2009; Ostrosky-Zeichner et al. 2010)

The antifungal agents available in the market have various drawbacks such as toxicity, a narrow spectrum of activity and fungistatic rather than fungicidal profiles. Some also exhibit drug-drug interactions. Secondly, currently available agents act on targets that are also found in mammalian cells. The discovery of antifungal agents that possess selective toxicity against the eukaryotic fungal cell remains an important scientific challenge. ${ }^{73}$

Ideally, a selectively toxic antifungal agent should be developed that interacts with a fungal target not found in other eukaryotic cells. This strategy involves selective inhibition of the biosynthesis of important structural elements in the fungal cell. Ergosterol, a major component of fungal plasma membrane is one such target
and polyenes, azoles, morpholines and allylamines act either on ergosterol or different enzymes involved in ergosterol synthesis. For instance, azoles inhibit $14 \alpha$-lanosterol demethylase in the ergosterol biosynthesis pathway leading to depletion of ergosterol and accumulation of intermediate C-14 methyl-substituted sterols (Fig. S1.8). ${ }^{70,74}$

Fig. S1.8: Mechanism of antifungal action of azoles

Ergosterol depletion leads to disruption of membrane integrity and subsequently, inhibition of the fungal pathogen (Fig. S1.8). Even with the advent of ketoconazole, the search for improved antifungal azole agents has continued due in part to concerns over the potential for toxicity and poor penetration into cerebrospinal fluid associated with ketoconazole. Fluconazole is the current drug of choice for the treatment of severe infections caused by the Candida species and Candida neoformans. However, Fluconazole has only weak activity against isolates of Aspergillus species. Some of the fluconazole derivatives exhibited significant variations in plasma pharmacokinetics besides having weak anti-aspergillus activity. ${ }^{75}$ Voriconazole also shows non-linear pharmacokinetics but has raised some concern with respect to its ocular toxicity. ${ }^{76}$

The continuing demand for safe and effective broad spectrum antifungal agents with favorable pharmacokinetic properties has spurred both the design and development of new systemically active antifungal triazoles. The chemistry of triazoles has received considerable attention in recent years due to their biological activity. The triazole moiety is stable to metabolic degradation and capable of hydrogen bonding, which could be favorable in binding biomolecular targets as well as in increasing solubility. Moreover, triazoles can function as attractive linker units which could connect two pharmacophores to give an innovative bifunctional drug, and thus have become increasingly useful and important in constructing bioactive and functional molecules. Additionally, many investigations have shown that the addition of alkyl chains and/or various aromatic substituents, especially containing halogen atoms, has an important effect on the antimicrobial activities. Secondly, as compared to imidazoles (clotrimazole, ketoconazole, miconazole), 1,2,3-triazoles are less susceptible to metabolic degradation and have much greater target specificity, increased potency and an expanded spectrum of activity. ${ }^{77}$ Therefore, the present work was initiated with an aim towards developing new $1,2,3$ triazoles with variable functional groups and having potent biological activity, especially antifungal activity. ${ }^{49}$

## 1B.2. Present Work

In recent years, studies have revealed that many of the cancer drugs have the potential to be anti-fungal agent vice versa anti-fungal compounds also show potential anti-cancer properties. ${ }^{78}$ For example, thiabendazole, an orally available antifungal drug in clinical use for 40 years, also potently inhibits angiogenesis in animal models and in human cells. Thiabendazole reversibly disassembles newly established blood vessels, marking it as a vascular disrupting agent (VDA) and thus as a potential complementary therapeutic agent for use in combination with current anti-angiogenic therapies. ${ }^{79}$

Figure 1B.1: Structures of the sub-structural units $\boldsymbol{A}-\boldsymbol{C}$ noticed in the azole-class of antifungals and of the two types of newly designed trizole scaffolds

Similarly, recent Phase II studies have revealed the anti-fungal azole drug itraconazole for advanced prostate cancer treatment. ${ }^{80}$ Having the building blocks of the newly developed 1,2,3-triazole anti-cancer hits in hand, we reasoned that a slight structural/functional group modification of 1ea keeping some of the key aspects of 1,2,4-triazole antifungals, shall lead to new anti-fungal compounds. In this context, two classes of 1,4-disubstituted 1,2,3-triazole compounds have been designed as
potential candidates for antifungal screenings. The following figure reveals the salient features of our design. A dissection of the traizole antifungals revealed three key central structural elements. We designed the compounds in such a way that in type-I, the commonly noticed $\mathbf{N - N}-\mathbf{C}-\mathbf{C - O H}$ (Structural Unit A, Fig. 1b.1) in all azoleantifungal compounds has been retained. Whereas in type-II, along with this, another structural unit N-C-C-C-OH (Structural Unit B, Figure 1B.1) has been also incorporated. ${ }^{76}$

## 1B.2.1. Chemistry:

## 1B.2.1.1 Synthesis of alkyne precursors for type-I triazoles

The aromatic alkynol intermediates ( $\mathbf{3} \mathbf{f}$ and $\mathbf{3 g}$ ) were synthesized by treating in situ prepared ethynylmagnesium chloride with two aromatic ketones such as acetophenone and propeophenone in THF respectively (scheme 1B.1). ${ }^{60}$ The structures were confirmed by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and IR. For example, in the ${ }^{1} \mathrm{H}$ NMR spectrum of compound $\mathbf{3 f}$, the acetylenic proton was identified as a singlet at $\delta 2.67$ ppm, the methyl protons $\left(\mathrm{CH}_{3}\right)$ resonated as singlet at 1.78 ppm and the quaternary hydroxyl proton appeared at $\delta 2.65 \mathrm{ppm}$ as a broad singlet. In the ${ }^{13} \mathrm{C}$ spectrum, the carbonyl carbon disappeared at $\delta 198 \mathrm{ppm}$ and the quaternary carbon atom appeared at $\delta 69.7 \mathrm{ppm}$ as singlet and the terminal acetylenic proton resonated at $\delta 73.0 \mathrm{ppm}$. The presence of the acetylenic group was also evident from the IR spectrum where the absorption was observed at $3318 \mathrm{~cm}^{-1}$.

Scheme 1B.1: Synthesis of alkyne precursors for Type-I

## 1B.2.1.2. Synthesis of aryl 1,4-substituted-1,2,3-triazolyl compounds (Type-I)

1,3 Dipolar cycloaddition of two different chloroazidophenols 5a and 5c with different alkynols $\mathbf{3 b}, \mathbf{3 e}, \mathbf{3 f}$ and $\mathbf{3 g}$ was carried out using the click reaction. One equivalent of alkynols $\mathbf{3 b}, \mathbf{3 e}, \mathbf{3 f}$ and $\mathbf{3 g}$ were taken in separate round bottom flasks and one equivalent of each chloroazidophenols 5a and 5c were dissolved in tbutanol/water (3:1) the resulting solution was treated with $20 \mathrm{~mol} \% \mathrm{CuSO}_{4} .5 \mathrm{H}_{2} \mathrm{O}$ and $20 \mathrm{~mol} \%$ sodium ascorbate. ${ }^{63}$ The reaction mixture was stirred at room temperature ( 6 h) for completion of cycloaddition leading to the final compounds 8ba, 8bc, 8ea, 8fc and 8ga (Scheme 1B. 2 and Fig. 1B.2).

All 1,2,3-triazolyl derivatives 8ba-8ga were characterized by IR, ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR and HRMS. For instance for $\mathbf{8 f c}$, the IR spectrum showed characteristic stretching frequencies at 3160 and $1443 \mathrm{~cm}^{-1}$. In the ${ }^{1} \mathrm{H}$ NMR spectrum, the methyl $\left(\mathrm{CH}_{3}\right)$ appeared at $\delta 2.02 \mathrm{ppm}$ as a singlet and the characteristic triazolyl proton appeared at $\delta 8.20 \mathrm{ppm}$ as a singlet. The remaining aromatic protons resonated between $\delta 6.96-7.63 \mathrm{ppm}$. In the ${ }^{13} \mathrm{C}$ NMR spectrum, the methyl $\left(\mathrm{CH}_{3}\right)$ appeared at $\delta$ 28.9 ppm as quartet and benzylic quaternary carbon appeared at $\delta 70.9 \mathrm{ppm}$ as a singlet. In the HRMS, the exact mass of the compound showed as calculated for $\mathrm{C}_{16} \mathrm{H}_{15} \mathrm{O}_{2} \mathrm{~N}_{3} \mathrm{Cl}[\mathrm{M}+\mathrm{H}]^{+}$was 316.0847 and it was found as 316.0846 . For another representative triazole $\mathbf{8 b} \mathbf{b}$, in the ${ }^{1} \mathrm{H}$ NMR spectrum, the benzylic CH appeared at $\delta$ 6.03 as singlet, methyl protons $\left(\mathrm{CH}_{3}\right)$ appeared as a singlet at $\delta 2.31 \mathrm{ppm}$ and the triazolyl proton appeared at $\delta 7.88 \mathrm{ppm}$ as a singlet. In the ${ }^{13} \mathrm{C}$ NMR spectrum, two methyl carbons appeared at $\delta 21.3 \mathrm{ppm}$ as quartet and the benzylic carbon appeared at $\delta 69.4 \mathrm{ppm}$. In the HRMS, the exact mass of the compound calculated for $\mathrm{C}_{17} \mathrm{H}_{17} \mathrm{O}_{2} \mathrm{~N}_{3} \mathrm{Cl}[\mathrm{M}+\mathrm{H}]^{+}$was 330.1004 and it was found as 330.1005 .

Scheme 1B.2: Preparation of Type-I triazoles

Figure 1B.2: Type-I 1,2,3-triazoles

## 1B.2.1.3. Synthesis of alkyne precursors for Type-II triazoles

The aromatic alkynol intermediates ( $\mathbf{9 a}$ and $\mathbf{9 g}$ ) were synthesized by treating propargyl bromide with aromatic aldehydes and ketones ( $\mathbf{2 a} \mathbf{-} \mathbf{2} \mathbf{j}$ ) under Zn - mediated Barbier reaction conditions (Scheme 1B.3). ${ }^{81}$

Scheme 1B.3: Synthesis of alkyne precursors for Type-II

The products were confirmed by ${ }^{1} \mathrm{H}$ NMR and IR. For example, in the ${ }^{1} \mathrm{H}$ NMR spectrum of compound 9 a the acetylenic proton was identified as a triplet at $\delta$ 2.05 ppm with $J=2.7 \mathrm{~Hz}$, the methylene protons resonated as a doublet of doublet at 2.61 ppm with $J=2.7,6.3 \mathrm{~Hz}$ and the benzylic CH appeared at $\delta 4.83 \mathrm{ppm}$ as a triplet with $J=6.3 \mathrm{~Hz}$. The presence of the acetylenic group was also evident from the IR spectrum wherein the absorption was observed at $3309 \mathrm{~cm}^{-1}$.

## 1B.2.1.4. Synthesis of Type-II 1,2,3-triazolyl compounds

Scheme 1B.4: Synthesis of $3^{\circ}$-alkynol derived 1,2,3 triazoles

The 1,3-dipolar cycloaddition of chloroazidophenols 5a and $\mathbf{5 c}$ with different alkynols $\mathbf{9 a}-\mathbf{9 g}$ (scheme 1B.3) were carried out under established CuAAc reaction conditions. One equivalent of alkynols $\mathbf{9 a - 9 g}$ taken in different round bottom flasks and one equivalent of chloroazidophenol 5a and $\mathbf{5 c}$ were dissolved in ${ }^{\mathrm{t}} \mathrm{BuOH} /$ water (3:1) and the resulting solution was treated with $20 \mathrm{~mol} \% \mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ and $20 \mathrm{~mol} \%$ of sodium ascorbate. The reaction mixture was stirred at room temperature ( 6 h ) for completion of cycloaddition leading to the final compounds $\mathbf{1 0}$ (scheme 1B. 4 and Fig. 1B.3). All 1,2,3-triazolyl derivatives 10aa-10gc were characterized by IR, ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR and HRMS. For the representative compound 10ba, the IR spectrum showed characteristic stretching frequencies at 3067 and $1645 \mathrm{~cm}^{-1}$. In the ${ }^{1} \mathrm{H}$ NMR spectrum of compound 10ba, the methyl- $\mathrm{H}\left(\mathrm{CH}_{3}\right)$ resonated at $\delta 1.61 \mathrm{ppm}$ as a singlet, methylene- $\mathrm{H}\left(\mathrm{CH}_{2}\right)$ appeared at $\delta 3.28 \mathrm{ppm}$ as a singlet and the triazolyl proton appeared at $\delta 7.83 \mathrm{ppm}$ as a singlet. In the ${ }^{13} \mathrm{C}$ NMR spectrum, the $\mathrm{CH}_{3}$ carbon resonated at $\delta 27.9 \mathrm{ppm}$ as a quartet, the methylene carbon appeared at $\delta 39.5 \mathrm{ppm}$ as a triplet and the benzylic carbon appeared at $\delta 73.0 \mathrm{ppm}$ as a singlet. In the HRMS, the exact mass of the compound showed as calculated for $\mathrm{C}_{17} \mathrm{H}_{17} \mathrm{O}_{2} \mathrm{~N}_{3} \mathrm{Cl}[\mathrm{M}+\mathrm{H}]^{+}$was 330.1004 and it was found to be 330.0999 .

Figure 1B.3: Type II 1,2,3-triazoles

After the successful synthesis of type-I and type-II 1,2,3-triazoles, we have proceeded further for their antifungal evaluation against some human fungal pathogens.

## 1B.2.2. Biology:

## 1B.2.2.1. Microorganisms and growth conditions

Human pathogens C. albicans ATCC 24433, C. albicans ATCC 10231, C. glabrata NCYC 388, C. neoformans, C. neoformans ATCC 34664, A. fumigatus MCC 1046, A. niger ATCC 10578 were maintained on YPG (yeast extract, $0.3 \%$; peptone, $0.5 \%$; and glucose, 1\%) agar slants, Whereas, Fusarium oxysporum (plant pathogen) was maintained on PD (potato, 20\%; dextrose, 2\%) agar slants at $4{ }^{\circ} \mathrm{C}$. Saccharomyces cerevisiae wild type and $S$. cerevisiae erg11 haploinsufficient mutant were a kind gift from Dr. A. Bacchawat, IISER, Mohali, India. The wild type and mutant S. cerevisiae strains were maintained on 2 x YPG agar slants. For different assays, the inoculum of the yeasts was prepared by growing them in YPG broth at $28^{\circ} \mathrm{C}$ for 24 h .

## 1B.2.2.2. Antifungal susceptibility assay

Antifungal activities of the synthesized compounds, type-I and type-II (in terms of Minimum Inhibitory Concentrations (MICs)) against C. albicans ATCC

24433, C. albicans ATCC 10231, C. glabrata NCYC 388, C. neoformans, C. neoformans ATCC 34664, A. fumigatus MCC 1046, A. niger ATCC 10578 (CLSI M27-A3) and F. oxysporum (CLSI M38-A2) were determined by broth microdilution assay with some modification. ${ }^{82}$ The only modification was that instead of RPMI1640, YPG medium was used as a growth medium. Briefly, appropriate amount of compounds were dissolved in dimethyl sulfoxide to get 100X final strength. The stock was then diluted 1:50 in YPG medium and $200 \mu \mathrm{l}$ from this was added to the first row of a 96-well microtitre plate.

The compounds were serially diluted two fold in successive wells to get a range of 1$128 \mu \mathrm{~g} / \mathrm{ml}$. Fungal yeast cells ( $\left.\sim 2 \times 10^{3} \mathrm{cfu} / \mathrm{mL}\right)$, freshly grown in YPG broth in logarithmic phase, were suspended in the medium and inoculated (100 $\mu \mathrm{l}$ ) in the wells of the plate. For $F$. oxysporum, $2 \times 10^{4}$ spores $/ \mathrm{mL}$ were added. The microtitre plate was incubated for 48 h , and the absorbance was measured at 600 nm by using the microtitre plate reader (xMark ${ }^{\mathrm{TM}}$ Microplate Absorbance Spectrophotometer, BioRad, CA, USA) to assess cell growth. The MIC was defined as the lowest concentration exhibiting $>90 \%$ inhibition of visible growth as compared to growth of the control. All the results were summarized in table 1B.1. Based on the MIC results, compounds 8bc, 10cc, 10fa, 10fc, 10ga, 10gc, and 10da were identified as lead molecules. Mechanism of antifungal action of these compounds was investigated by different assays.

## 1B.2.2.3. Haploinsufficiency assay for identification of ergosterol synthesis inhibitors

A yeast genome-wide drug induced haploinsufficiency screen using S. cerevisiae as a model organism has been developed by Giaever et al. ${ }^{83}$ Lowering the dosage of a single gene from two copies to one copy in diploid yeast results in a heterozygote. The resulting mutant strain becomes sensitive to any drug that acts on the product of this gene as compared to wild type strain. This haploinsufficient phenotype thereby identifies the gene product of the heterozygous locus as the likely drug target. ${ }^{84}$

For instance, diploid wild type $S$. cerevisiae strain and its mutant (haploid for the targeted gene erg11 - lanosterol $14 \alpha$-demethylase gene) were used for the screening of the ergosterol synthesis inhibitors. As the mutant has only one copy of $\operatorname{erg} 11$, the effect of azole inhibitors (targeting ergosterol synthesis) on growth will be more pronounced on it as compared to the wild type, whereas other agents will exert similar effect on both the strains. The synthesized compounds were checked for antifungal activity against both $S$. cerevisiae strains in 2X YPG medium by broth microdilution assay (CLSI M27-A3). ${ }^{82}$ (Table 1B.2). Concentration of compounds 10ca, 10fa, 10ga required to inhibit growth of the mutant was half than the concentration required for wild type S . cerevisisae growth inhibition identifying lanosterol $14 \alpha$-demethylase as their target.

Table 1B.2: Haploinsufficiency assay for target identification using $S$. cerevisiae wild type and mutant for ergll gene

## 1B.2.2.4. Effect of the compounds on sterol profile of C. albicans ATCC 24433

The depletion of ergosterol as a result of inhibition of the lanosterol $14 \alpha$-demethylase by the compounds was quantified by spectrophotometry ${ }^{85}$. Briefly, overnight grown C. albicans ATCC $24433\left(1 \times 10^{6} \mathrm{cfu} / \mathrm{ml}\right)$ cells were inoculated in a series of flasks with 50 ml of YPG broth containing 0.5 MIC and MIC of the compounds 10ca, 10fa, 10ga, 8bc, 10da and Fluconazole. The flasks were incubated on a rotary shaker (180 $\mathrm{rpm}, 30^{\circ} \mathrm{C}$ ) for 24 h . After incubation, the cells were harvested by centrifugation (3000rpm for 5 min ) and washed with sterile distilled water. The net wet weight of the cell pellet was determined. Three ml of $25 \%$ alcoholic potassium hydroxide solution
( 25 g of KOH and 35 ml of sterile distilled water, brought to 100 ml with $100 \%$ ethanol), was added to 125 mg of pellet and vortex mixed for 1 min . Cell suspensions were transferred to sterile borosilicate glass screw-cap tubes and were incubated in an $85^{\circ} \mathrm{C}$ water bath for 1 h . Following incubation, tubes were allowed to cool to room temperature. Sterols were then extracted by addition of a mixture of 1 ml of sterile distilled water and 3 ml of $n$-heptane followed by vigorous mixing for 3 min . The heptane layer was scanned between 220 and 300 nm with a spectrophotometer (Spectrascan UV-2600 Spectrophotometer, Chemito).

Figure 1B.4: Sterol profile of C. albicans ATCC 24433 in presence of a) 10ca, b) 10fa, c) 10ga and d) fluconazole

The presence of ergosterol and the late sterol intermediate 24(28)DHE in the extracted sample resulted in a characteristic four-peaked curve. A dose-dependent decrease in the height of the absorbance peaks was evident and corresponded to decreased ergosterol concentration for fluconazole and 10fa, 10ga and 10ca. The sterol profile for negative control compounds $\mathbf{8 b c}$ and $\mathbf{1 0 d a}$ was similar to control. The results confirmed lanosterol $14 \alpha$-demethylase enzyme as a target for these compounds, thereby exerting their antifungal action through ergosterol depletion.

For compounds 8bc, 10cc, 10fc, 10gc, 10da and no ergosterol depletion was observed, which indicated a different mode of action. Apart from lanosterol $14 \alpha-$ demethylase inhibition, few azoles like miconazole are known to exert their antifungal action by reactive oxygen species (ROS) generation. Therefore ROS production was evaluated for these compounds by using dichlorofluorescin diacetate dye.

## 1B.2.2.5. Detection of Reactive Oxygen Species (ROS) production

Intracellular reactive oxygen species (ROS) generation was assessed by $2^{\prime}, 7^{\prime}-$ dichlorofluorescein diacetate (DCFH-DA) staining. After incubation of the cells with different concentrations of the compounds for $120 \mathrm{~min}, 10 \mu \mathrm{M}$ DCFH-DA in Phosphate Buffer Saline (PBS) was added and incubated further for 30 min . The cells were then harvested, washed with PBS and directly viewed using epifluorescence microscope (Leitz Laborlux S, Germany) equipped with a 50 W mercury lamp and a filter set (I3 filter block with excitation filter BP 450-490, and suppression filter LP520). The digital images were acquired with a Canon Power shot S80 camera and Zoom Browser EX 5.5 software for image acquisition and management. The percentage of fluorescent cells for each treatment was determined from the total number of cells ( $>300$ ) and the fluorescent cells counted.

Fig.1B.5: DCFH-DA staining of C. albicans ATCC 24433 cells exposed to A) 32 $\mu \mathrm{g} / \mathrm{ml} \mathrm{10da}$; B) $64 \mu \mathrm{~g} / \mathrm{ml}$ 10cc; C) $64 \mu \mathrm{~g} / \mathrm{ml} 10 f \mathrm{c}$ and D) $64 \mu \mathrm{~g} / \mathrm{ml}$ 8bc.

Based on these experiments the compounds 10cc, 10ge, 10fc, 10da and 8be were found to show antifungal activity through the ROS generation. For compound

10 gc ROS generation was not observed. Compounds 10da and 10fc were most effective and showed ROS generation in $>99 \%$ cells at 2 X MIC 4 X MIC concentration, respectively.

## 1B.2.3. Analysis

Based on the results obtained from the anti fungal studies of selected compounds, screening against some of the fungal pathogens followed by the mode of action such as enzyme inhibition and/or reactive oxygen species (ROS) generation and the structural features of the lead compounds following are some important observations need to be highlighted. First, as expected, compounds of Type II having the structural units $\mathbf{A}$ and $\mathbf{B}$ have shown better antifungal activity when compared with the Type 1 compounds which are having the structural units $\mathbf{A}$ and $\mathbf{C}$.

Figure 1B.6. Structure activity relationship of type I and II azoles
The results are indicative of the importance of a flexible methylene $\left(\mathrm{CH}_{2}\right)$ linker in between the two aryl ring for better antifungal activity. Another interesting and important feature that we noticed was how the position of the halo group changed the mode of action. When the chloro group was at the C-5 position of the phenyl ring (or meta) to the triazole unit, the molecule (compounds 10fa and 10ga) inhibited the fungal pathogen through the inhibition of enzyme, lanosterol $14 \alpha$-demethylase. Whereas, when the chloro group was at para position of the phenyl ring to the triazole
unit (compounds $\mathbf{1 0 c c}, \mathbf{1 0 f c}$ and $\mathbf{8 b c}$ ), the inhibition of the fungi was due to ROS generation. Interestingly, for 10da, though the chloro group was at C-5 position of the phenyl ring (or meta) to the triazole unit, ROS generation was observed as antifungal mode of action, which might be due to the presence of long alkyl chain at benzylic junction. The structure activity relationship will be useful in further optimization of lead molecules.

## 1B.2.4.1. Synthesis of dialkyne with $\mathbf{3}^{\mathbf{0}}$-hydroxy group

After having a couple of antifungal hits in hand, we next turned our attention towards the synthesis of another set of compounds which were designed mainly around the antifungal drug fluconazole. The structure of the fluconazole is characterized by the presence of a 1,3-di(1H-1,2,4-triazol-1-yl)propan-2-ol unit. We were interested to synthesize ditriazolyl compounds and see whether the addition of another triazole unit has any significant advancement.

Scheme 1B.5: Synthesis of dialkynol
Scheme 1B.5, saliently describes the synthesis of symmetric dialkynols dialkynol $\mathbf{9 a - 9} \mathbf{c}$. The synthesis started with the reactions of alkynones $\mathbf{4 a}, \mathbf{4 b}$ and $\mathbf{4 e}$ with excess ethynyl magnesium chloride in THF. However modest yields were obtained in Grignard reaction. The non-symmetric dialkynol 9d was synthesized from alkynone $\mathbf{4 a}$ by treating it with propargyl bromide under Zn -mediated Barbier reaction conditions (Scheme 1B.5). The structures of the dialkynol compounds (9a-

9d) were confirmed by NMR and IR spectroscopy. In the ${ }^{1} H$ NMR spectrum of the compound 9a, the terminal alkyne two protons were resonated at $\delta 2.79 \mathrm{ppm}$ as singlet and the hydroxyl proton was resonated at $\delta 3.23 \mathrm{ppm}$ while aromatic protons were resonated in between $\delta 7.36-7.84 \mathrm{ppm}$ as two multiplets.

## 1B.2.4.2. Synthesis of aryl bis(1,4-substituted-1,2,3-triazolyl) compounds

Next the dialkynols $9 \mathbf{a - 9 d}$ were subjected for the $\mathrm{Cu}(\mathrm{I})$ catalyzed 1,3-cycloaddition reaction strategy with azidophenols $\mathbf{5 a}, \mathbf{5 b}, \mathbf{5 c}$ and $\mathbf{5 e}$ to afford a set of eight triazoles (Scheme 1B.6).

Scheme 1B.6: Synthesis of bis triazoles
All 1,2,3-triazolyl derivatives 12aa-12ce were characterized by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR and HRMS. For the representative compound 12da, in the ${ }^{1} \mathrm{H}$ NMR spectrum, the methylene proton appeared as two doublet at $\delta 3.80 \mathrm{ppm}$ and $\delta 3.99 \mathrm{ppm}$ with $J=$ 14.9 Hz , respectively and the two triazolic protons were resonated as two separate singlets at $\delta 7.85$ and $\delta 8.31 \mathrm{ppm}$ respectively. In ${ }^{13} \mathrm{C}$ NMR spectrum the methylene carbon resonated at $\delta 38.3 \mathrm{ppm}$ as triplet and the benzylic quaternary carbon appeared at $\delta 73.5 \mathrm{ppm}$ as singlet. In the HRMS, the exact mass of the compound showed as calculated for $\mathrm{C}_{24} \mathrm{H}_{19} \mathrm{O}_{3} \mathrm{~N}_{6} \mathrm{Cl}_{2}\left(\mathrm{M}^{+}+\mathrm{H}\right)$ was 509.0890 and it was found as 509.0891.

The anti-fungal activity of all the bis triazoles was checked against the fungal pathogens as described in section 1B.2.2.2. All the symmetric bis-triazoles (Fig.1B.4) were ineffective as anti-fungals. The only unsymmetric bis-triazole 12da showed antifungal activity with MIC values of 16,16 and $8 \mu \mathrm{~g} / \mathrm{ml}$ for C. albicans ATCC 24433, C. glabrata NCYC 388 and C. neoformans ATCC 34664, respectively. Similar MIC ( $32 \mu \mathrm{~g} / \mathrm{ml}$ ) for S. cerevisiae wild type and ergll mutant indicated that
mode of the action for 12da was different than inhibition of lanosterol $14 \alpha$ demethylase enzyme.

Figure 1B.7: Synthesized bis 1,2,3-triazoles

## Conclusion:

To conclude, three sets of compounds have been designed by integrating some of the key structural elements present in the azole antifungals in the structure of one the novel anti-cancer hit that we have identified. Screening of focused collection of newly synthesized 1,2,3-triazoles lead to identify a couple of hits having promising antifungal activities. The mechanistic investigations revealed the possibility of twocomplimentary modes of action for these 1,2,3-triazole derivatives. Further investigations on SAR of this new series of hits are currently under progress.

General experimental procedure B: To a solution of alkyne (9 or 3) (1.0 eq.) and azide 5 (2.2 eq.) in ${ }^{\mathrm{t}} \mathrm{BuOH}: \mathrm{H}_{2} \mathrm{O}$ (3:1) at rt, sodium ascorbate ( 0.95 eq.) and $\mathrm{CuSO}_{4}$ $5 \mathrm{H}_{2} \mathrm{O}$ ( 0.2 eq.) were added and the resulting brick reddish mixture was stirred vigorously for 6 hrs. The reaction mixture was diluted and extracted with EtOAc. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvents were evaporated under reduced pressure. The product was purified by column chromatography.

## 4-Chloro-2-(4-((3,5-dimethylphenyl)(hydroxy)methyl)-1H-1,2,3-triazol-1-

$\mathbf{y l}$ )phenol (8ba): Isolated by column chromatography (pet.ether/ $\mathrm{AcOEt}=6: 4, \mathrm{R}_{f}=$ 0.3 ). The title compound was determined as colourless solid (86\%). ## CHAPTER II:

[Pd]-Catalyzed Cycloisomerization: Synthesis of benzofuran conjugated sugar/nucleoside derivatives

### 2.1. Introduction:

Benzofurans are a class of highly privileged structural motifs of heterocyclic compounds existing widely in natural products and unnatural synthetic compounds with biological and pharmacological potential. ${ }^{1}$ They have been found to exist in nature since the late $19^{\text {th }}$ century. ${ }^{2}$ Since that time their investigations have revealed many avenues of understanding their properties. The simple benzofuran heterocyclic compound consists of fused benzene and furan rings, which is usually extracted from coal tar.

Figure S2.1: The basic benzofuran motif

### 2.1.1. Over view of benzofuran

### 2.1.1.1. Benzo[b]furan in natural products

Benzo[b]furan (Later it has been described as benzofuran) is the parent of many related compounds with more complex structures, particularly in a myriad number of natural products. ${ }^{3}$ In particular many of these natural products are biologically more active than Egonol, and it has a wide spectrum of biological activities including insecticidal, fungicidal, antimicrobial, antisweet, antiproliferative, cytotoxic and antioxidant properties. ${ }^{4}$ In nature's collection of biologically active benzofurans, 2-heteroarylbenzofuran ring systems are widely distributed in nature and have been reported to have antiviral, antioxidant and antifungal activities. For example, cicerfuran, obtained from the roots of a wild species of chickpea, Cierbijugum, was reported to be a major factor in the defense system against Fusarium wilt. ${ }^{5}$ The similar type of natural products such as Furomollugin, Viniferifuran, Anigopreissin A are also of biological significance. ${ }^{6}$ Most of the benzofuran containing natural products are known for their cytotoxic and antitumor activity, such as Rubicordifolin and its analogous. The highly substituted benzofuran contain novel oligostilbenes, such as malibatol $A$ and $B$, viniferifuran and

Shoreaphenol and exhibit a wide variety of pharmacological activities including antiinflammatory, antioxidant, antifungal, antibacterial, anti-HIV, and anticarcinogenic activities. The marine natural products such as Liphagal, show PI3K signaling inhibitory activity and Frondosin B plays an important role in tumor progression and metastasis in several human cancers, including lung cancers. ${ }^{7}$

Figure S2.2: Wide spectrum of Benzofuran containing natural products

### 2.1.1.2. Benzofuran in Pharmaceuticals

Benzofuran derivatives are an important class of heterocyclic compounds that exhibit biological activity on a wide range of targets. ${ }^{8}$ The synthetic and natural benzofuran derivatives are best known for their pharmaceutical potential. Recently, benzofurans have been identified as selective adenosine $\mathrm{A}_{2 \mathrm{~A}}$ receptor antagonists ${ }^{9}$ for a novel nondopaminergic approach to PD therapy and nonacidic benzofuran EP1 receptor antagonists for the treatment of inflammatory pain. ${ }^{10}$ The unnatural benzofuran scaffold, Aminodarone and its synthetic analog Dronedarone were found as antiarrhythamatic agent, available in the market with different trade names. ${ }^{11}$ There are several benzofuran containing molecules that have showed anti tumor activity, such as CRA-024781, found as a novel synthetic inhibitor of histone
deacetylase enzymes with antitumor activity in vitro and in vivo. Befunolol is a betaadrenoceptor blocking agent, which is clinically used in the treatment of glaucoma,which is available under different trade names in the market. The natural product Psoralen and its isomers have shown very good biological activity, a case in point being the important use of psoralen is in PUVA treatment for skin problems such as psoriasis. Angelicin has shown antiviral property. Inparticular, the natural product, Coumestrol also shows pharmaceutical, because of its estrogenic activity. ${ }^{12}$

Figure S2.3: Molecules containing the benzofuran motif

### 2.1.1.3. Benzofuran in Functional materials

Benzofuran is known for its wonderful structure, it expands from organic chemistry to the interdisplinary field of science. Despite its applications in biological systems and pharmaceutics, it has shown several applications in the field of material science as well. ${ }^{13}$ Finally, benzofurans have also emerged recently as important structural elements for organic materials, such as organic transistors. Some of the benzofuran derivatives have shown optoelectronic properties, Benzodifuran (BDF) derivatives developed as organic light-emitting diode (OLED) devises have demonstrated that BDFs function as efficient hole transporting materials (HTMs). ${ }^{13 \mathrm{c}}$ The benzotrifuran has also shown very good optoelectronic properties. The recent results indicated that the benzofuran based polymeric material PBDFDODTBT is a
promising candidate for high-efficiency polymer solar cells and the benzo[1,2-b:4,5$b^{\prime}$ ]difuran unit may be an excellent electron donating building block for organic electronic materials. ${ }^{14}$ Benzofuran-containing oligoaryls are known to be highly fluorescent and good hole transporting materials. Small molecules and conjugated polymers based on benzofuran chromophores have been used for electroluminescent devices, solar cell applications, and field effect transistors. ${ }^{15}$

In particular, benzodifuran (BDF), is of prime interest as organic semiconductors due to their fascinating features including structural symmetry and planarity, as well as rigid and $\pi$-extended conjugation which can enhance electron delocalization and intermolecular interactions to improve charge mobility.

### 2.1.2. Synthetic strategies towards benzofurans:

The widespread occurrence and important biological-/material applications associated benzofuran derivatives has led to the development of a broad range of methods for their synthesis. All the known methods for the synthesis of benzofurans can be arranged into two groups. The first group involves the formation of an annulated heterocyclic ring (in this case furan) by the intramolecular cyclization of benzene derivatives. The methods of the second group are encountered very rarely and involve the creation of an annulated carbocyclic ring. In this chapter, mainly the methods of the first group followed by few examples of the second group are going to be discussed. Coming to the first group - i.e annulation of the furan ring, the methods can be grouped in the following four possible types depending upon the bond which is being constructed. Following are some representative examples selected for each group.

Figure S2.4: Strategy for the benzofuran construction

### 2.1.2. 1. Ring closure by the formation of the $\mathbf{O} \mathbf{- C} \mathbf{2}$ bond (Type-I)

The majority of the condensation methods involve the formation of $\mathrm{C} 2-\mathrm{O}$ bond, which belongs to the first type. The starting compounds are ortho-substituted phenols. Substituents at the ortho position must contain an electron-deficient $\beta$-carbon atom, which is the structural unit of some unsaturated fragment or is attached to an atom characterized by a sufficiently strong $M$ effect. In literature, there are a large number of reports of this type of approach. Some notable ones are mentioned below.

Kotschy et al. reported a simple one-pot procedure for the preparation of substituted benzofurans starting from acetylated halogenated phenols and their coupling with a suitable alkyne and subsequent base-mediated saponification and cyclization. This method has been applied successfully to the total synthesis of natural products such as Cicerfuran and dehydrotremetone (S1.C and S1.F, scheme S2.1 respectively). ${ }^{16}$

Scheme S2.1: Kotschy's approach for the Cicerfuran and dehydrotremetone
A mercury-mediated cycloetherification of o-alkynylphenylmethyl ethers has been reported by Chern and coworkers in the synthesis of ailanthoidol, XH-14, and obovaten.

Scheme S2.2: Chern's approach for the synthesis of ailanthoidol

In this synthetic strategy 2-substituted phenyl-3-chloromercuriobenzofuran could be a key intermediate for the successful synthesis of these natural products (Scheme S2.2). ${ }^{17}$

Ling-Yi Kong et al. have developed an unusual rearrangement of a benzopyran group to a benzofuran group during a synthesis of coumarins to obtain new candidates for treating Alzheimer's disease (AD). The rearrangement ocurred under moderate conditions such as piperazine substituents reacted with S3.A in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ in acetone and ethanol at reflux temperature for 48 h and offered a facile and practical preparation of biologically active benzofuran derivatives(Scheme S2.3). ${ }^{18}$

Scheme S2.3: Kong's approach for the benzofuran derivatives
Lei Zhou et al. described a general and practical method for synthesizing 2substituted benzofurans. This method employs easily accessible $N$-tosylhydrazones and $o$-alkynylphenols as substrates. The reaction proceeds through a CuBr -catalyzed coupling-allenylation-cyclization sequence under ligand-free conditions. In this reaction, a di-substituted allene intermediate is formed via the migratory insertion of a copper carbene species, which smoothly undergoes copper-catalyzed intramolecular cyclization to afford 2-substituted benzofurans (Scheme S2.4). ${ }^{19}$

Scheme S2.4: Zhou's approach for the Cu catalyzed benzofuran derivatives

Zhen Yang and coworkers reported the carbonylative annulation of $o$ alkynylphenols mediated by $\mathrm{PdCl}_{2}\left(\mathrm{PPh}_{3}\right)_{2}$ and dppp in the presence of CsOAc and CO leading to functionalized benzo[b]furo[3,4-d]furan-1-ones in good yields. This novel synthetic approach provides a highly efficient method for diversification of the benzofuran scaffold for combinatorial synthesis (Scheme S2.5). ${ }^{20}$

S5.A

Scheme S2.5: Yang's approach for the synthesis of benzofuran derivatives
Hashmi et al. demonstrated the gold-catalyzed phenol synthesis of an intramolecular migration of the oxygen atom which leads to the doubly annulated benzofuran derivatives. In this strategy, the oxygen atom is transferred intramoleculary and also the reaction proceeds through cationic intermediates (Scheme S2.6). ${ }^{21}$

Scheme S2.6: Hashmi's approach for the gold-catalyzed benzofuran derivatives
Miura and coworkers reported a copper-mediated annulative direct coupling of $o$-alkynylphenols with $1,3,4$-oxadiazoles. This proceeds smoothly even under ambient conditions to afford the corresponding biheteroaryls. The conditions employed involve the use of $\mathrm{CuF}_{2} /$ phen as catalyst with the experiments being conducted in the presence of $\mathrm{K}_{3} \mathrm{PO}_{4}$ in DMF at rt and in the open atmosphere. The reaction system represents a new avenue for the construction of biheteroaryl molecules of interest in their biological and physical properties (Scheme S2.7). ${ }^{22}$

Scheme S2.7: Cu-catalyzed benzofuran synthesis
Marko et al. have reported a unique approach for the synthesis of highly functionalized benzofurans employing the base-catalyzed ( ${ }^{t} \mathrm{BuOK}$ ) condensation of $o$ hydroxyphenones with 1,1-dichloroethylene. As shown in the following scheme S2.8, initially this leads to the formation of the corresponding chloromethylene furans. These labile intermediates undergo a facile rearrangement into benzofuran carbaldehydes under mild acidic conditions. ${ }^{23}$

Scheme S2.8: Marko's approach for synthesis of benzofuran
Wood and coworkers have demonstrated a strategy for the synthesis of Diazonamide A. The strategy commenced with commercially available hydroxycinnamate S9.A, which was converted into the olefin S9.B after few steps. Reductive ozonolysis followed by dehydration of the resulting hemiacetal S9.C afford benzofuran S9.D, a very versatile intermediate, which leads to the Diazonamide A after few steps (Scheme S2.9). ${ }^{24}$

Scheme S2.9: Wood's approach for the synthesis of Diazonamide $A$
Wang et al. reported a base promoted synthesis of 2-substituted benzofurans from 2-alkynylphenols. These cyclizations were carried out with $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ in DMF at $60^{\circ} \mathrm{C}$ for 1 h . The deprotonation of the phenol hydroxyl group by a base was probably the driving force for the reaction (Scheme S2.10). ${ }^{25}$

Scheme S2.10: Wang's approach for the base catalyzed benzofurans synthesis
Wesby et al. reported that the 3-halocoumarins are readily converted into benzofuran-2-carboxylic acids via a Perkin (coumarin-benzofuran ring contraction) rearrangement reaction. This rearrangement entails initial base catalyzed ring fission. The resulting phenoxide anion then attacks a vinyl halide to produce the final benzofuran moiety and this reaction was explored under microwave reaction conditions (Scheme S2.11). ${ }^{26}$

Scheme S2.11: Wesby's approach for coumarin-benzofuran ring contraction

Zhangjie Shi et al. reported recently the first example of copper-mediated oxidative annulations of phenols and unactivated internal alkynes to afford benzofuran derivatives. Starting from commercially available phenols and alkynes, the direct one step/pot synthesis of benzofuran derivatives has been achieved with high efficiency. The mechanistic pathway indicates that the process is likely to initiate with the reversible electrophilic carbocupration, followed by alkyne insertion and cyclization to afford the desired product (Scheme S2.12). ${ }^{27}$

Scheme S2.12: Shi's approach for Cu-catalyzed benzofurans synthesis

### 2.1.2.2. Ring closure by the formation of the $\mathbf{C}(2)-\mathrm{C}(3)$ bond (Type-II)

Gao et al. described a method which offers a straight forward and facile synthetic route for the preparation of a variety of 2-benzofuranyl-6,7-methylenedioxyquinoline-3-carboxylic acids via the one-pot reaction of ethyl 2-chloromethyl-6,7-methylenedioxyquinoline-3-carboxylate (S13.B) with various substituted salicylaldehydes (Scheme S2.13). Most of these products are anticipated have high biological significance. ${ }^{28}$

Scheme S2.13: Gao's approach for the synthesis of benzofuran darevatives

Jumbam et al. reported the titanium-mediated synthesis of 2,3disubstitutedbenzofurans via McMurray coupling of esters of $o$-hydroxyacetophenone derivatives. Despite the fact that this reaction requiresstoichiometric amounts of the titanium reagent, however, is the method of choice for the synthesis of 2,3disubstitutedbenzofurans (Scheme S2.14). ${ }^{29}$

Scheme S2.14: Jumbam's approach for the synthesis of benzofuran darevatives
Wang and coworkers developed a ring closing metathesis (RCM) method for the synthesis of benzofurans. The metathesis reaction of various O -vinyl and C propenylphenyl as precursor (S15.A) proceeded smoothly with the Grubbs' $1^{\text {st }}$ generation catalyst to furnish the desired benzofurans in high yields (Scheme S2.15). ${ }^{30}$

Scheme S2.15: Wang's approach for the synthesis of benzofuran darevatives
A concept funded upon the "sequential homobimetallic catalysis- $a$ process in which two different complexes of the same metal, but in two different oxidation states, promote two catalytic cycles in sequence" Gabriele et al, reported a simple approach for the synthesis of 2-benzofuran-2-ylacetamides. The conditions employed involve the treatment of a mixture of 1-(2-allyloxyaryl)-2-yn-1-ols (S16.A), amines, and CO with catalytic amounts of $\mathrm{PdI}_{2}$ in conjunction with $\mathrm{PPh}_{3}$ and KI (Scheme S2.16). ${ }^{31}$

Scheme S2.16: Gabriele's approach for the synthesis of benzofuran darevatives

Kumar et al. reported an efficient and simple strategy for the synthesis of 2,3diarylbenzofurans involving Pd-catalyzed one pot arylation cum intramolecular oxycyclization of o-hydroxystyrene derivatives. This approach involves a sequence of hydroarylation of phenols and alkynes in the presence of $\operatorname{In}(\mathrm{OTf})_{3}$ under microwave irradiation followed by a one-pot Heck-oxyarylation of generated 1 -substituted-Rhydroxy styrenes and trapping of the intermediate organometallic species with aryl halides leading to a 2,3-diarylbenzofuran (Scheme S2.17). ${ }^{32}$

Scheme S2.17: Kumar's approach for sequential In and Pd catalyzed synthesis of 2,3disubstituted benzofuran darevatives

### 2.1.2.3. Ring closure by the formation of the Ar-C(3) bond (Type-III)

Youn et al. developed one-pot procedures for the conversion of allyl aryl ethers to 2-methylbenzofurans via sequential Claisen rearrangement and oxidative cyclization. The employed conditions for the reaction involve the use of $\mathrm{Pd}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{Cl}_{2}$ as catalyst,benzoquinone as the oxidation agent (Scheme S 2.18 ). ${ }^{33}$

Scheme S2.18: Youn's approach for the synthesis of benzofuran darevatives
Rajgopal et al. reported a practical and an alternative approach for the synthesis of (2-butyl-5-nitrobenzofuran-3-yl)(4-hydroxyphenyl)methanone, a key intermediate used in the preparation of the antiarrhythmic drug, Dronedarone hydrochloride. The base (TEA) mediated intramolecular nucleophilic displacement of 2-bromo-1-(2-hydroxy-5-nitrophenyl)hexan-1-one has been used as the key reaction in this approach. Accordingly, the 2-butyl-5-nitrobenzofuran (S19.B) was prepared in
$70-75 \%$ of yield after two steps. This key intermediate has been taken forward for the preparation of Dronedarone (Scheme S2.19). ${ }^{34}$

Scheme S2.19: Rajgopal's approach for the synthesis of benzofuran darevatives

Liu et al. described a regioselective protocol for the synthesis of 3carbonylated benzofuran (3-CBF) involving the gold(III)-catalyzed tandem condensation/rearrangement/cyclization reaction of $O$-arylhydroxylamines with 1,3dicarbonyl compounds. The best feature of this strategy is the minimum loading of catalyst ( $3 \mathrm{~mol} \%$ of $\mathrm{AuCl}_{3} / \mathrm{AgSbF}_{6}$ ) and a highly selective protocol for the synthesis of 3-CBFs (Scheme S2.20). ${ }^{35}$

Scheme S2.20: Liu's approach for the synthesis of benzofuran darevatives
Maddaluno and Le Strat reported a simple route to 3-vinylbenzofurans via the internal addition of aryl-anions on the triple bond and the subsequent anionic cascade.

Scheme S2.21: Maddaluno's approach for the synthesis of 3-vinylbenzofurans

As shown in scheme S 2.21 , the iodine-lithium exchange with an excess of n BuLi followed by a 5-exo-dig addition of the aryllithium on the triple bond leads to a vinyllithium intermediate which after loss of lithium ethoxide leads to an exocyclic allene. The intermediate exocyclic allene then rearranges to 3-vinylbenzofuran. ${ }^{36}$

Yin et al. described a novel method for the synthesis of functionalized benzofurans from furans. This protocol involves palladium (0)-catalyzed dearomatizing C 2 arylation of the furan ring, the formation of a $\pi$-allylic palladium complex, furan ring opening, and $\beta$-hydride elimination, resulting in a benzofuran derivative (Scheme S2.22). ${ }^{37}$

Scheme S2.22: Yin's method for the synthesis benzofurans
Wang et al. reported a Pd-catalyzed synthesis of 3-vinylbenzofurans. Interestingly the key step involved in this approach is the migratory insertion of the Pd carbine B to form intermediate C , which subsequently undergoes a $\beta$-hydride elimination. Notably, in this transformation, C-Csingle bond formation (the cyclization) and the $\mathrm{C}=\mathrm{C}$ double bond formation (carbene coupling) have been achieved in a single catalytic cycle (Scheme S2.23). ${ }^{38}$

Scheme S2.23: Wang's approach for the synthesis of 3-vinylbenzofurans

Werz et al. reported a novel domino reaction of diynyl-substituted bromoarenes leading to highly functionalized benzofuran systems through a sequence of $\mathrm{C}-\mathrm{C}$ bond formations. In the mechanistic study the two consecutive carbopalladation steps were anticipated, but it is not clear so far whether double bond isomerization as followed by a sigmatropic rearrangement or the involvement of $\mathrm{Pd}(\mathrm{IV})$ species is assumed. A slight change of the substrates opened another reaction pathway resulting in the annulation of benzene moieties (Scheme S2.24). ${ }^{39}$

Scheme S2.24: Werz's method for the synthesis of 3-substituted benzofurans

Ma et al. reported a palladium (0)-catalyzed cascade reaction for the efficient synthesis of 3-vinylbenzofuran derivatives (S25.C) employing the benzyne chemistry. In this method,first, the benzyne intermediate was formed in situ upon the treatment of S25.A with CsF; an instant intramolecular ene reaction produces readily allene intermediate, obviously due to the aromaticity of the benzene ring; the insertion reaction with ArPdI forms a $\pi$-allylic palladium intermediate and the subsequent $\beta-\mathrm{H}$ elimination would afford the unexpected isomeric benzofuran derivative S25.C. ${ }^{40}$

Scheme S2.25: Ma's method for the synthesis of 3-substituted benzofurans

### 2.1.2.4. Ring closure by the formation of the Ar-O bond (Type IV)

Pandey et al. reported the synthesis of 2-sustituted benzofurans. The enolates of 2-aryl-1-substituted ethane-1-ones S26.A can undergo photo-induced intramolecular
cyclization to form 2-substituted benzofurans S26.C. The general reaction procedure involved uses a 125 W mercury lamp to irradiate a mixture of S26.A and 1,4dicyanonaphthalene $(\mathrm{DCN})$ in a molar ratio of approximately $10: 1$, at $>230 \mathrm{~nm}$ in a Pyrex filter. A mixture of acetonitrile and water (8:2), with sodium hydroxide added to bring the pH to $\sim 10$, was used as the solvent. ${ }^{41}$

Scheme S2.26: The photo-induction methodology of Pandy et al.

### 2.1.2.5. Synthesis from furans and dihydrofurans

Scheme S2.27: Liebeskind's approach for Pd catalyzed benzofuran synthesis

4-Chloro-2-cyclobutanone S27.A can undergo Pd-catalysed cross-coupling with 2stannylated furans S27.B, followed by heating, to give 4-hydroxybenzofurans S27.C. (Scheme S2.27) S27.C was easily prepared in good yield by reacting 4-Chloro-2cyclobutanone S27.A with 2-(tri-n-butylstannyl)furan In the presence of $5 \mathrm{~mol} \%$ $\mathrm{Pd}(\mathrm{PhCN})_{2} \mathrm{Cl}_{2}$ and $10 \mathrm{~mol} \%$ tris-2-furylphosphine acted as the Stille cross-coupling catalyst in the first step of the reaction, which proceeded at $50^{\circ} \mathrm{C}$ for 4 hours and at $100{ }^{\circ} \mathrm{C}$ for another 4 hours. (Dioxane was used as the solvent). The overall yield of this reaction was $94 \%{ }^{42}$

### 2.2. Introduction:

Carbohydrates are the most abundant organic compounds in living organisms and account for one of the four major biomolecular classes including proteins, lipids, and nucleic acids. ${ }^{44}$ Before the 1970s, scientists solely considered carbohydrates as energy sources, structural components, and protective agents. Inparticular, they serve as fuel molecules as well as fundamental constituents of living organisms. ${ }^{45}$ However recent scientific innovations have revealed that carbohydrates play an important role in many biological functions. In the living cells, the carbohydrates play key roles in many crucial recognition processes. It has been realized that these compounds may provide important leads for drug discovery. ${ }^{46}$ To reveal the biological roles of saccharides, it is very important to have sufficient amounts of pure and well-defined (poly)saccharides of different sizes and compositions. The chemical synthesis of oligosaccharides is much more complicated than the synthesis of other biopolymers such as peptides and oligonucleotides and many challenging problems still need to be addressed.

Figure S2.5 Natural Nucleosides having other than ribo sugar part and some important nucleoside-based anti-HIV agents

In recent years, the mimicking of carbohydrates for the synthesis of better drug candidate as well as organic materials has drawn major attention from both academia and industry. ${ }^{47}$ The interaction of sugars with proteins initiates many biological processes. One can achieve control of these processes by using sugar-like structures to antagonize the natural ligands at the protein receptor level. Nucleoside analogues are pharmacologically diverse family that includes cytotoxic compounds, antiviral agents and immunosuppressive molecules. ${ }^{47}$ Considerable progress has been
made in the search for novel nucleoside structures with anticancer and/or antiviral activity by modifications in the nucleo base and/or in the sugar moiety and several branched-chain sugar nucleosides have shown potent antitumor activity.

eq. 1
3 C-C bonds two rings at the last steps

simultane $\mathrm{C}-\mathrm{C}$ and C -O bond formation at the last step

Figure 2.1: C-3' modified nucleosides
Nucleosides are glycosylamines consisting of a nucleobase bonded to a ribose or deoxyribose sugar. Nucleosides can be phosphorylated by specific kinases in the cell on the sugar's primary alcohol group, producing nucleotides, which are the molecular building block of DNA and RNA. In medicine, several natural nucleosides and their analogues are used as antiviral or anticancer agents (Fig. S2.5). ${ }^{48-52}$ The sugar modifications, in particular, C-3' modified sugar unit in the nucleosides, have gained significant attention for therapeutic development. In 1992, Camarasa et al. produced an entirely new class of molecules, designated as TSAO ([2,5-bis-O-(tert-butyldimethylsilyl)- $\beta$-D-ribofuranosyl]-3-spiro-5'-(4'-amino-1',2'-oxathiole $2^{\prime}, 2^{\prime}-$ dioxide)), which showed potent HIV-1 inhibitory activity. ${ }^{53}$ The prototype compound is TSAO-T, in which the simple modification is at C-3' position (Fig. 2.1). From this initial success, later few groups focused on the synthesis of C-3' modified nucleosides for antiviral and anticancer evaluation. ${ }^{54,55}$ These agents behave as antimetabolites that interact with a number of intracellular targets blocking the DNA chain elongation
or interfering with the biosynthesis of nucleosides and nucleotides, a limiting process in cell proliferation.

### 2.3. Present Work

In our group, earlier, we had reported a modular approach for the synthesis of a focused collection of C3 isobenzfuran-spiroannulatedribo-configured nucleosides either in furanose or in pyranose forms. As shown in Figure 2.1 (eq. 1), the key reaction employed was alkyne cyclotrimerization and more importantly, this reaction was conducted on a free nucleoside diyne. ${ }^{56}$ Since this reaction was executed as the last step and one of the partners is a simple alkyne, this provided an opportunity for synthesizing a large collection of C3' modified nucleosides. Our strategy is quite striking as the other spironucleosides in general are synthesized in a target oriented route - i.e one approach for one nucleoside. In continuation, we have been interested at looking at the possibility of appending a benzofuran unit at C3', considering that fact that it occurs in diverse natural, medicinally important compounds such as drug candidates and organic materials.

Figure 2.2: Selected sugar alkynols $15 a-15 d$ and possible cyclization with 15a
Coming to our synthetic plan, amongst the several methods available in the literature for the synthesis of the benzofuran unit, the coupling-cum-cyclization of oiodophenols with alkynes in particular (both being catalyzed by various metal complexes) has attracted our attention. We have intended this strategy to explore the
target cum flexibility to make the combinatorial library of desired product collection in an efficient manner. This method is a mild one with tolerance for various functional groups. It also provides an opportunity for synthesizing diverse analogues by simple variation of either the iodophenol $\mathbf{1 4}$ employed (final event) or the nucleobase used (just two steps prior to the final event). The salient features of our approach are described in Figure 2.1 (eq. 2). ${ }^{57}$

As a first step in this direction, to establish a platform for the final cyclization event on an unprotected nucleobase, we have set up our first objective to check the feasibility of this reaction with simple sugar alkynols. As shown in Figure 2.2, we have different sugar alkynols $\mathbf{1 5 a} \mathbf{- 1 5 d}$ having free -OH groups at different positions that we have selected as model substrates in this context. The possible cyclizations of one of the important alkynol 15a' are given in Figure 2.2. This reveals our concern in this regard and also why these model studies are important in the direction of conducting the projected benzofuran unit synthesis via the coupling-cum-cyclization of o-iodophenols with the free nucleoside alkynol. There exist three possibilities. If the $\mathrm{C} 5-\mathrm{OH}$ participates in the cyclization, depending upon the mode of cyclization i.e 5 -exo or 6 -endo, it leads to two possible ketals i.e. either a bridged bicyclic ketal (eq. 3, Fig. 2.2) ${ }^{58}$ or a spiroketal (eq. 1, Fig. 2.2). ${ }^{59}$ In case if the Ar-OH participates in the cyclization, it provides the desired benzofuran 13aa. ${ }^{57}$ Indeed, the sugar alkynol 15a will serve as the starting point for our synthesis of key nucleoside alkynols. Having set the initial objectives, we proceeded next for the synthesis of the key alkynols 15a15d from the suitable sugar precursors. ${ }^{59,} 60$

Our journey started with the preparation of known the xylose derived alkynol 1a from D-xylose in 5 steps. The key [Pd]-mediated Sonogashira coupling of the xylose derived alkynol 15a with o-iodophenol 14a proceeded smoothly and provided exclusively one single product in $85 \%$ yield. ${ }^{61}$ The conditions employed involve the use $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}(5 \mathrm{~mol} \%)$, as a catalyst along with $\mathrm{PPh}_{3}$ ( $5 \mathrm{~mol} \%$ ), and CuI (5 mol\%) in a mixture of $\mathrm{Et}_{3} \mathrm{~N}$ and DMF and the reaction was conducted at rt . The structure of isolated product was determined as the desired benzofuran derivative 13aa with the help of spectral and analytical data. For example, in the ${ }^{1} H$ NMR spectrum of 13aa, the characteristic $\mathrm{C}(3)-\mathrm{H}$ of the benzofuran ring is present at $\delta 6.63$ ppm as a singlet and the 2 H of the methylene unit appeared as doublets at $\delta 2.86$ and $\delta$ 3.13 ppm with a large geminal coupling $(15.5 \mathrm{~Hz})$. As expected, the $\mathrm{C}(3)$ of the
benzofuran ring resonated at up field ( $103.5 \mathrm{ppm}, \mathrm{d}$ ) and the methylene unit attached to the $\mathrm{C}(2)$ appeared at $\delta 30.5 \mathrm{ppm}$.

Scheme 2.1: The intended cycloisomerization and the synthesis of sugarbenzofuran conjugates. Reaction conditions and reagents: a) $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}($ $5 \mathrm{~mol} \%$ ), $\mathrm{PPh}_{3}$ ( $5 \mathrm{~mol} \%$ ), $\mathrm{CuI}(5 \mathrm{~mol} \%), \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMF}$, rt

Having established the key benzofuran synthesis with the complicated model substrate 15a, our next objective was to show the generality of this reaction by varying both the coupling partners i.e. iodophenol and the sugar alkynol. The sugar alkynols 15b-15d having the alkynol integrated on different sugar platforms have been synthesized by following the established procedures. Scheme 2.2 provides a glimpse of the protocols that we have adopted for their syntheses. ${ }^{59,60}$

Scheme 2.2: Preparation of sugar alkyne precursors

The iodophenols $\mathbf{1 4 a}-\mathbf{1 4 c}$ have been selected as the partners for conducting the Pd-catalyzed coupling-cum-cyclization with the sugar alkynols 15a-15d and thus establish the generality of this reaction in the direction of the synthesis of sugar derived benzofuran conjugates. As shown in Scheme 2.3, the Sonogashira coupling of sugar alkynol, 15a-15d with the three iodophenols $\mathbf{1 4 a}-\mathbf{1 4 c}$ proceeded smoothly in the presence of $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}, \mathrm{CuI}$ and $\mathrm{Et}_{3} \mathrm{~N}$ in DMF at rt within 6 h . The reactions are facile with all the four alkynes employed and gave the corresponding sugar-
benzofuran conjugates in very good yields. The substituents on the iodophenol in general have no influence on the yields except in case of the $\mathrm{NO}_{2}$ group where the yields dropped slightly. All the new compounds synthesized have been fully characterized by using spectroscopic techniques and the results have been summarized in Scheme 2.3.

Scheme 2.3: Scope of [Pd]-catalyzed benzofurannulation of sugar derivatives.

### 2.2.1 Synthesis of glycosyl donor (18).

After successful implementation of the target cum flexibility strategy employing the [Pd]-catalyzed benzofuran synthesis on simple sugar derivatives, we intended to check the feasibility of this reaction with unprotected $\mathrm{C}(3) \mathrm{C}$ propargylated nucleosides $\mathbf{1 5 g}$ and $\mathbf{1 5 h}$. The modification of the sugar unit in the nucleosides is one of the promising approaches for the derivation of new antiviral agents. Our initial intention was to carry out this benzofurannulation reaction on free nucleosides $\mathbf{1 5 g}$ and $\mathbf{1 5 h}$, thereby making a provision of substrate flexibility at the final stage and providing an easy access for synthesizing a collection of $\mathrm{C}\left(3^{\prime}\right)$ modified nucleosides (Scheme 2.5). The synthesis of the key intermediate alkynyl nucleosides $\mathbf{1 5 g}$ and $\mathbf{1 5 h}$ started from the known xylose derived alkynol 15a.

We have earlier established that if the $\mathrm{C} 5-\mathrm{OH}$ is free and undergoes the hydrolysis and peracetlyation, in general it leads to a pyranose derivative. However, we have handled this problem by protecting the $\mathrm{C} 5-\mathrm{OH}$ with an acid stable protecting
group and then carrying out the acetonide hydrolysis with acid followed by peracetylation, which exclusively leads to a desired furanose derivative. ${ }^{56}$ We intended to follow a similar approach in the present case as well. Thus the selective protection of $\mathrm{C}(5)-\mathrm{OH}$ of alkynol $\mathbf{1 5 a}$ as its pivaloate $\mathbf{1 6}$ has been carried out by using pivaloyl chloride in the presence of triethyl amine in dichloromethane. The resulting compound 16 has been subjected for the selective hydrolysis of the 1,2acetonide group by employing $70 \% \mathrm{AcOH}$ in water reflux for 6 h to offer the anomeric mixture of intermediate lactols $\mathbf{1 7}$, which have been subsequently subjected for peracetylation employing acetic anhydride in the presence of triethyl amine (TEA) and DMAP in dichloromethane to furnish a 1:1anomeric mixture of triacetyl C(3)propargyl ribose derivatives 18 (scheme 2.4).

Scheme 2.4: Reagents and conditions: a) Piv-Cl, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 4 \mathrm{~h}$; b) $70 \% \mathrm{ACOH}$, reflex 6 h ; c) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 4 \mathrm{~h}$.

The compound 18 was fully characterized by spectral and analytical data. In the ${ }^{1} \mathrm{H}$ NMR spectrum of compound 18, the methylene unit appeared as two doublet of doublets at $\delta 2.88 \mathrm{ppm}$ and 3.05 ppm with a large geminal coupling $(J=2.5,17.7$ $\mathrm{Hz})$ and the methyl protons of pivaloyl appeared at $\delta 1.07 \mathrm{ppm}$ as a singlet and the methyl protons of acetate appeared at $\delta 1.91,1.92$ and 1.95 ppm as singlets respectively. In the ${ }^{13} \mathrm{C}$ NMR spectrum, the alkyne carbons and quaternary carbon $\mathrm{C}(3)$ showed at $\delta 82.3,82.2$ singlet and doublet respectively and the methylene carbon at $\delta 21.1 \mathrm{ppm}$. The remaining carbonyl quaternary carbons appeared as singlets at $\delta 168.5,168.7,168.9$ and 177.1 ppm . The acetylenic $\mathrm{C}-\mathrm{H}$ stretching frequency was appeared at $3308 \mathrm{~cm}^{-1}$ and the $\mathrm{C} \equiv \mathrm{C}$ stretching frequency at $2121 \mathrm{~cm}^{-1}$ in the IR spectrum of compound 18.

After successful synthesis of the anomeric mixture of triacetates 18, our next concern was the $N$-glycosidation. The glycosidation of triacetate $\mathbf{1 8}$ was carried out under modified Vorbrüggen conditions. ${ }^{62}$ The conditions employed involve the treatment of $\mathbf{1 8}$ with thymine or with 5 -flurouracil in the presence of $\mathrm{N}, \mathrm{O}$ bis(trimethilsilyl)acetamide and TMSOTf in acetonitrile, then after completion at $0^{\circ} \mathrm{C}$ and then heating the contents at $50^{\circ} \mathrm{C}$ for 2 h to afford the protected nucleosides $\mathbf{1 5 e}$ and $\mathbf{1 5 f}$ respectively. The anomeric configuration of the protected nucleosides $\mathbf{1 5 e}$ and $\mathbf{1 5 f}$ was established with the help of spectral data analysis.

Scheme 2.5: a) BSA, TMSOTf, $\mathrm{CH}_{3} \mathrm{CN}, 4 \mathrm{~h}$; b) $\mathrm{NaOMe}, \mathrm{MeOH}, \mathrm{rt}, 20 \mathrm{~min}$.
For example, in the ${ }^{1} \mathrm{H}$ NMR spectrum of compound $\mathbf{1 5 e}$, the anomeric- H and $\mathrm{C}(2)-\mathrm{H}$ resonated at $\delta 6.19$ and 5.45 respectively as a doublets with a characteristic large $J_{1,2}$ coupling constant $J=7.8 \mathrm{~Hz}$ which is indicative of a $\beta$-configutration. The characteristic C-3 $\mathrm{CH}_{3}$ appeared at $\delta 1.92$ as singlet and the $\mathrm{C}-2$ olefinic proton resonated at down field $\delta 7.24$ as a singlet.The two protons of $\mathrm{CH}_{2}$, which were adjacent to alkyne $\left(\mathrm{CH}_{2}\right.$ of propargyl) resonated as two separate doublet of doublets at $\delta 3.04$ and $\delta 3.25$ with a coupling constant $J=2.5,17.3 \mathrm{~Hz}$. The amide N-H of 15e showed a broad singlet at $\delta 9.35 \mathrm{ppm}$. In the ${ }^{13} \mathrm{C}$ NMR spectrum of compound $\mathbf{1 5 e}$, the C-3 appeared as singlet at $\delta 112.0$ and C-2 olefin proton appeared as a doublet at $\delta$ 134.3 ppm . Quite interestingly, in the case of $\mathbf{1 5 f}$, the anomeric-H appeared as a doublet of doublet at $6.19\left(\mathrm{dd},{ }^{5} J_{(\mathrm{H} 1, \mathrm{~F})}=1.5,7.8 \mathrm{~Hz}\right)$ while it was a doublet in the case ofcompound $\mathbf{1 5 e}$. The second coupling was due to the long range coupling with a fluorine atom. The other couplings associated with the fluorine have been seen both in ${ }^{1} \mathrm{H}$ and the ${ }^{13} \mathrm{C}$ NMR spectra of compound $\mathbf{1 5 f}$. The deacetylation of $\mathbf{1 5 e}$ and $\mathbf{1 5 f}$ employing catalytic amounts of NaOMe in methanol gave the free alkynol
nucleosides $\mathbf{1 5 g}$ and $\mathbf{1 5 h}$ (Scheme 2.5) in good yields. The spectral data of the free nucleoside alkyne $\mathbf{1 5 g}$ and $\mathbf{1 5 h}$ were in accordance with the assigned structure. For example, the disappearance of characteristic peaks of pivaloyl, acetyl methyl group in ${ }^{1} \mathrm{H}$ NMR spectra was supportive of the assigned structures of $\mathbf{1 5 g}$ and $\mathbf{1 5 h}$.

### 2.2.2. Synthesis of Nucleoside derived benzofuran conjugates

Our initial experiments dealing with the Sonogashira coupling reaction of alkyne $\mathbf{1 5 g}$ (Scheme 2.6) were unsuccessful under the conditions described in Schemes 2.1 and 2.3.

Scheme 2.6: The substrate and reaction optimization for the synthesis of benzofuranconjugated nucleosides.

Optimization of the reaction conditions has been carried out by changing the reagents. Initial attempts at replacing the base TEA with $\mathrm{Cs}_{2} \mathrm{CO}_{3}, \mathrm{~K}_{2} \mathrm{CO}_{3}$ or with $\mathrm{Na}_{2} \mathrm{CO}_{3}$ met failure.

Scheme 2.7: The synthesis of benzofuran-conjugated nucleosides.
Next we moved to look at the amount of CuI as all the -OH groups are free and also the presence of free base. When 1 eq of CuI was employed, we could see the formation of the desired products with the help of mass spectra analysis. However, the conversion was unsatisfactory. When we switched to 2eq. CuI, the Sonogashira reaction provided the desired 19ea in $10 \%$ yield, despire the fact that the conversion
was about $63 \%$. Finally, when 3 eq of CuI was employed, the product 19ea was isolated in $27 \%$ yield and disturbingly; the conversion was almost $100 \%$. These experiments revealed that the presence of 3 equivalents of copper iodide (with respect to the alkyne) is essential and it indicated that activation of this alkyne required a stoichiometric amount of CuI. Despite the fact that the yield was poor ( $27 \%$ ), the isolation of pure nucleosides turned out to be a difficult proposition as the samples are always contaminated with the triethylamine salts. Considering these difficulties, we next moved to the corresponding protected nucleosides $\mathbf{1 5 e}$ and $\mathbf{1 5 f}$. Our preliminary experiments with the Sonogashira coupling of $\mathbf{1 5 e}$ with simple $o$-iodophenol (14a) revealed that even in this case, the presence of 3 equivalents of CuI is essential for obtaining the corresponding benzofuran 13ea in respectable yields.

Table 2.1. Generalization of the benzofuran synthesis on nucleoside templates
The compound 13ea was fully characterized by spectral and analytical data. In the ${ }^{1} \mathrm{H}$ NMR spectrum of compound 13ea, the characteristic benzofuran $\mathrm{C} 3-\mathrm{H}$ appeared at $\delta 6.43$ as singlet and the disappearance of alkyne proton was observed. The remaining aromatic protons resonated in the range of $\delta 7.20-7.50 \mathrm{ppm}$. The C3'$\mathrm{CH}_{3}$ appeared as singlet at $\delta 1.94$. The methylene $\left(\mathrm{CH}_{2}\right)$ protons, which are adjacent to the benzofuran appeared as two separate doublets at $\delta 3.15$ and 4.13 with a large germinal coupling of $J=15.3 \mathrm{~Hz}$. In the ${ }^{13} \mathrm{C}$ NMR spectrum of compound 13ea, the
benzofuran C 3 carbon resonated at $\delta 110.8$ as a doublet and the remaining aromatic carbons were also observed at the expected positions.

Subsequently, we conducted the Sonogashira coupling of $\mathbf{1 5 e}$ and $\mathbf{1 5 f}$ with the other iodophenols $\mathbf{1 4 a} \mathbf{- 1 4 c}$. All the reactions were facile and afforded the corresponding benzofurans in good yields and the details of all these reactions are summarized in Table 2.1. All the compounds were completely characterized with the help of analytical and spectroscopic techniques.

Table 2.2. Generalization of the benzofuran synthesis on nucleoside templates
The global deprotection of the resulting nucleoside conjugated benzofuran derivatives was carried out under Zemplan's conditions ( NaOMe in MeOH ) to afford the corresponding fully deprotected benzofuran conjugated nucleosides (19ea, 19eb, $19 \mathrm{ec}, 19 \mathrm{fa}, 19 \mathrm{fb}, 19 \mathrm{fc}$ ) in good yields. The details of the synthesis of all these compounds have been summarized in Table 2.2. The structures of all the compounds were confirmed with the help of analytical and spectroscopy techniques. For example, the disappearance of the characteristic peaks of the pivaloyl, acetyl methyl group in ${ }^{1} \mathrm{H}$ NMR was supportive of the assigned structures of $\mathbf{1 9 e a} \mathbf{- 1 9 f c}$.

## Conclusion

To conclude, the suitability of [Pd]-mediated coupling cum cyclization of oiodophenols with alkynes leading to benzofurans has been examined on various sugar and nucleoside derived alkynes. The reactions of sugar alkynes proceeded smoothly under the standard Sonogashira conditions employing both palladium and copper complexes in catalytic amounts. However, with the nucleoside derived alkynes, the presence of 3 equivalents of copper salt (with respect to the alkyne) is essential. Since the key benzofuran ring construction was the penultimate step in the synthesis of $C(3)$-modified nucleosides, and since it is an intermolecular coupling event, the present approach provides ample room for the synthesis of the corresponding benzofuran conjugated nucleosides collection.

### 4.3. General procedure for benzofuran synthesis

To a solution of alkyne ( 1.0 mmol ), iodophenol $(1.0 \mathrm{mmol})$ in $\mathrm{Et}_{3} \mathrm{~N}(5.0 \mathrm{~mL})$ and DMF ( 2.5 $\mathrm{mL}), \mathrm{PPh}_{3}(0.05 \mathrm{mmol})$ was added followed by $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}(0.05 \mathrm{mmol})$, and the reaction mixture was flushed with argon for 30 min . $\mathrm{CuI}(0.05 \mathrm{mmol})$ was added and flushed with argon for 10 min and stirred at rt for 6 h . The reaction mixture was partitioned between ethyl acetate and water. Then the organic layer was separated, washed with brine, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated. The crude residue was purified by column chromatography.

## 1,2-O-Isopropylidene-3-C-prop-2-ynyl-5-O-pivaloyl- $\alpha$-D-ribofuranose (16):

At $0^{\circ} \mathrm{C}$ a solution of compound $\mathbf{1 5 a}(9.9 \mathrm{~g}, 0.043 \mathrm{~mol})$, TEA ( $12.1 \mathrm{ml}, 0.08 \mathrm{~mol}$ ) and catalytic DMAP in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(150 \mathrm{ml})$ was treated with pivaloyl chloride ( 5.35 $\mathrm{ml}, 65.0 \mathrm{mmol}$ ) stirred at rt for 3 h . The reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and quenched with water and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. Combined organic phase washed with sat. $\mathrm{NaHCO}_{3}$ and water, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. Purification of the
 residue by silica gel column chromatography (pet.ether/ $\mathrm{AcOEt}=4: 1, \mathrm{R}_{f}=0.4$ ) gave compound 16 ( $86 \%$ yield) as a pale yellow syrup. $[\alpha]_{\mathrm{D}}{ }^{25}:+19.9$ (c $3.0, \mathrm{CHCl}_{3}$ ); IR (CHCl3): $v$ 3488, 3278, 2979, 2123, 1958, 1731.6, 1481, 1284, 1166, 1006, 874, 757, $642 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR ( $200 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 1.08(\mathrm{~s}, 9 \mathrm{H}), 1.26(\mathrm{~s}, 3 \mathrm{H}), 1.46(\mathrm{~s}, 3 \mathrm{H}), 2.03(\mathrm{t}, J=2.5 \mathrm{~Hz}, 1 \mathrm{H}), 2.24$ (dd, $J=17.2,2.5 \mathrm{~Hz}, 1 \mathrm{H}$ ), 2.42 (dd, $J=17.2,2.5 \mathrm{~Hz}, 1 \mathrm{H}), 3.05(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 3.95(\mathrm{dd}, J=3.5$, $11.0 \mathrm{~Hz}, 1 \mathrm{H}$ ), $4.04(\mathrm{dd}, J=4.5,7.2 \mathrm{~Hz}, 1 \mathrm{H}), 4.19$ (dd, $J=3.3,12.1 \mathrm{~Hz}, 1 \mathrm{H}), 4.37$ (d, $J=3.8$ $\mathrm{Hz}, 1 \mathrm{H}), 5.71(\mathrm{~d}, J=3.8 \mathrm{~Hz}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $50 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 22.4(\mathrm{t}), 26.2(\mathrm{q}), 26.3(\mathrm{q})$, 26.8 (q, 3C), 38.4 (s), 61.3 (t), 71.5 ( s), 78.0 (s), 78.9 (d, 2C), 81.3 (d), 103.4 (d), 122.2 (s), 177.8 (s) ppm; ESI-MS m/z: 335.14 (11\%, [M+Na] ${ }^{+}$), 351.11 ( $100 \%$, [M+K] $]^{+}$); Anal. Calcd for $\mathrm{C}_{16} \mathrm{H}_{24} \mathrm{O}_{6}$ : C, $61.52 ; \mathrm{H}, 7.74 \%$; found $\mathrm{C}, 61.54 ; \mathrm{H}, 7.73 \%$.

## 3-C-(2-Propynyl)-5-O-pivaloyl- $\alpha / \beta$-d-ribofuranose (17):

Compound 16 ( $11.6 \mathrm{~g}, 0.037 \mathrm{~mol}$ ) in $60 \%$ acetic acid $(100 \mathrm{~mL})$ was heated under reflux temperature for 2 h . The maximum acetic acid was removed by using reduced pressure, then the reaction mixture was neutralized by slow addition of solid $\mathrm{K}_{2} \mathrm{CO}_{3}$ and extracted in ethyl acetate. Combined ethyl acetate extracts were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$. and filtered and concentrated under reduced pressure. Purification
 of the residue by silica gel column chromatography $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{CH}_{3} \mathrm{OH}=9: 1, \mathrm{R}_{f}=0.6\right)$ gave a mixture of triol 17 ( $91 \%$ yield) as a colorless syrup.. IR $\left(\mathrm{CHCl}_{3}\right)$ : v 3434.0, 3308.9, 2974.0, $2121.8,1957.6,1728.6,1481.3,1285.2,1158.6,859.85,758.1,666.7 \mathrm{~cm}^{-1} ;{ }^{1} \mathrm{H}$ NMR (200 $\mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 1.21$ (s, 9 H ), $2.15(\mathrm{t}, J=2.6 \mathrm{~Hz}, 1 \mathrm{H}), 2.51$ (dd, $\left.J=2.8,17.2 \mathrm{~Hz}, 1 \mathrm{H}\right), 2.68$ (dd, $J=2.6,17.2 \mathrm{~Hz}, 1 \mathrm{H}), 3.24(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 3.42(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 4.05-4.23(\mathrm{~m}, 2 \mathrm{H}), 4.31-4.42$ (m, $2 \mathrm{H}), 5.07(\mathrm{~d}, J=6.8 \mathrm{~Hz}, 1 \mathrm{H}) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $50 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 24.4(\mathrm{t}), 27.1(\mathrm{q}, 3 \mathrm{C}), 38.7$ (s), $62.8(\mathrm{t}), 72.0(\mathrm{~d}), 74.2(\mathrm{~d}), 77.6(\mathrm{~s}), 78.7(\mathrm{~s}), 82.3$ (d), $96.0(\mathrm{~d}), 178.2$ (s) ppm; ESI-MS: $\mathrm{m} / \mathrm{z} 295.1222(31 \% \mathrm{M}+\mathrm{Na})$, $311.0832\left(100 \%[\mathrm{M}+\mathrm{K}]^{+}\right)$. Anal. Calcd for $\mathrm{C}_{13} \mathrm{H}_{20} \mathrm{O}_{6}: \mathrm{C}$, 57.34 ; H, 7.40\%; found C, 57.28 ; H, $7.34 \%$.

## 1,2,3-Tri- $O$-acetyl-3-C-(2-propynyl)-5-O-pivaloyl- $\alpha / \beta$-D-ribofuranose (18):

The triol 17 was dissolved in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(150 \mathrm{~mL})$. TEA ( 8 mL ) and catalytic DMAP was added and the mixture was cooled to $0{ }^{\circ} \mathrm{C}$. To this, acetic anhydride ( $6.8 \mathrm{~mL}, 0.072 \mathrm{~mol}$ ) was added and the contents were stirred at $0{ }^{\circ} \mathrm{C}$ for 1 h and then at room temperature for 1 h . The reaction mixture was neutralized slow addition of sat. $\mathrm{NaHCO}_{3}$ and
 extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and filtered and concentrated under reduced
pressure. Purification of the residue by silica gel column chromatography (pet.ether/ $\mathrm{AcOEt}=$ $\left.4: 1, \mathrm{R}_{f}=0.3\right)$ gave a mixture of triacetates $\mathbf{1 8}(88 \%$ yield $)$ as a colorless syrup. ## Genaral procedure for N -glycosidation

A solution of acetate $\mathbf{1 8}$ ( 2.51 mmol ), nucleobase ( 5.02 mmol ), and $\mathrm{N}, \mathrm{O}$-bis(trimethylsilyl) acetamide ( $3.06 \mathrm{~mL}, 12.54 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{3} \mathrm{CN}(15 \mathrm{~mL})$ was heated to reflux for 15 min . The reaction mixture was cooled to $0^{\circ} \mathrm{C}$ and TMSOTf ( $932 \mu \mathrm{~L}, 5.0 \mathrm{mmol}$ ) was added. The reaction mixture was stirred at $50{ }^{\circ} \mathrm{C}$ for 2 h , quenched with cold aq. $\mathrm{NaHCO}_{3}$ and extracted with EtOAc. The combined organic layer was washed with water, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and filtered and concentrated under reduced pressure. Purification of the residue by silica gel column chromatography.

## 1-[2,3-Di-O-acetyl-3-C-propynyl)-5-O-pivaloyl- $\beta$-D-ribo-pentofuranosyl]thymidine (15e):

Isolated by column chromatography (pet.ether/ $\mathrm{AcOEt}=7: 3, \mathrm{R}_{f}$ $=0.3$ ). ## General procedure for global deprotection of esters

A solution of 13ea-13fc ( 1.0 mmol ) and catalytic NaOMe in methanol $(5 \mathrm{~mL})$ was stirred at room temperature for 20 min . The reaction mixture was concentrated under reduced pressure and the crude was purified by silica gel column chromatography.

## CHAPTER III:

[Ru]-Catalyzed C-H activation: Synthesis of antiinflammatory 2-aroylbenzofurans via linear/branched selective acrylate insertion

### 3.1. Introduction

The construction of C-C bond is central to the Organic Synthesis. Since the first synthesis of urea in the laboratory by Wöhler in 1828, the organic chemists were searching for more efficient, economic methods to construct the $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{H}$, and $\mathrm{C}-$ hetero atom bonds for the value added products. ${ }^{1}$ The progression of aldol reaction, Claisen and related condensations are the initial breakthroughs in this arena which amply explored the potential of carbonyl compounds and active methylene groups. ${ }^{2}$ Subsequently, the Zn -mediated addition of $\alpha$-bromoesters (Reformatsky reaction) ${ }^{3}$ and allyl-, propargyl halides (Barbier reaction) ${ }^{4}$ have revealed that functionalized yet not active methylene groups can be also added to the carbonyl compounds. The pioneering work of Grignard on organomagnesium reagents made new insights in organic synthesis by efficient construction of $\mathrm{C}-\mathrm{C}$ bond and it utilized for synthesis of complex organic molecules. ${ }^{5}$ The pre and post Grignard reaction, there has been numerous classical organic transformations taken place in $19^{\text {th }}$ and $20^{\text {th }}$ centuries and which are paved the way for the development of modern organic synthesis. ${ }^{6}$

The shining light had been blink, as the transition metal complexes utilized for the cultivation of $\mathrm{C}-\mathrm{C}$ and C -hetero atom bond formation. ${ }^{7}$ The post Ullmann reaction, copper metal complexes efficiently used for the construction of $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-$ hetero atom bond with prefunctional aromatic compounds. ${ }^{8}$ Despite its good catalytic properties, advances in organocopper chemistry, still there is a large number of other problems persist. For example, the reactions were sluggish and involved homo couplings. The mid and late $20^{\text {th }}$ century has witnessed for many changes, a long range of transition and organometallic complexes, such as $\mathrm{Cu}, \mathrm{Ni}$ or Pd , used as catalysts for myriad of organic transformations for $\mathrm{C}-\mathrm{C}$ and C -hetero atom bond formation. ${ }^{7,9}$ The palladium complexes occupied the major room for $\mathrm{C}-\mathrm{C}$ bond formation by cross coupling reactions, such as Heck, Suzuki, Negishi, Sonogashira and Stille reactions and their modifications. ${ }^{10}$ These Pd-catalyzed reactions are addressed the molecular complexity in the synthesis of organic molecules. Despite their low catalyst loading and high catalytic activity, there are several limitations were associated. For example all these catalysts are working on only pre-functional aromatic and aliphatic compounds.

In the late $20^{\text {th }}$ and early $21^{\text {st }}$ century chemists have aggressively searching for new efficient, economic and environment friendly method for the organic
transformations. A long range of early and late transition metals have been used, finally succeeded and introduced the word C-H bond activation and functionalization, which brings the great revolution and it provides a sustainable alternative to both traditional cross coupling and classical Friedal-Craft's alkylation. ${ }^{11}$ In particular, a variety of methods have been developed to allow for the formation of a number of types of bonds, including $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{H}, \mathrm{C}-\mathrm{N}, \mathrm{C}-\mathrm{O}, \mathrm{C}-\mathrm{S}$, and $\mathrm{C}-\mathrm{P}$. These developments have allowed for the synthesis of myriad complex molecules in a manner never before possible.

### 3.1.1. Cross Coupling Reactions with Acrylate

Transition metal catalyzed cross coupling reactions with acrylates have been developed as an important tool for constructing new carbon-carbon bonds in modern organic synthesis, to accomplish the synthesis of natural products, pharmaceuticals, dyes, organic conductors and semi-conductors, polymers and many value added industrial applications. ${ }^{7}$ Among the many reactions, first foremost, Heck reaction is well known transformation of aryl/heteroaryl halide and acrylate into olefinated adducts. ${ }^{12}$ One of the benefits of the Heck Reaction is its outstanding trans selectivity. In the early 1970s, Heck reported that acrylates could be arylated by reacting with stoichiometric amounts of Ar-Pd-X or Ar-Pd-OAc complexes. Recent developments in the catalysts and reaction conditions have resulted in a much broader range of donors and acceptors being amenable to the Heck Reaction.

Scheme S3.1: $\operatorname{Pd}(O A c)_{2}$ catalyzed Heck reaction with acrylates

A mechanism was proposed which involved a syn migratory insertion of the olefin into the arylpalladium species, followed by a syn $\beta$-hydride elimination of a hydridopalladium [HPdX] ( $\mathrm{X}=\mathrm{Cl}$, OAc) (Scheme S3.2). Subsequently, a reaction using organo-palladium salts, formed by the direct reaction of aryl iodides with finely divided palladium, to react with acrylate (alkene) was developed by Heck, and discovered independently by Mizoroki at the same time. This discovery opened the way to a new reaction later it called the Mizoroki-Heck reaction. ${ }^{13}$

Scheme S3.2: Catalytic cycle for Heck reaction

### 3.1.2. $\mathrm{C}-\mathrm{H}$ activation

Over the years based on these initial studies, a broad range of new reaction conditions were developed to directly transform $\mathrm{C}-\mathrm{H}$ bonds into $\mathrm{C}-\mathrm{C}$ or $\mathrm{C}-$ heteroatom bonds via $\mathrm{C}-\mathrm{H}$ activation by avoiding the pre-functional groups. ${ }^{11}$ These $\mathrm{C}-\mathrm{H}$ activation reactions brought the tremendous change, by shorting the synthetic routs in modern organic synthesis by utilizing ubiquitous $\mathrm{C}-\mathrm{H}$ bonds. This $\mathrm{C}-\mathrm{H}$ functionalization is a class of reactions that could lead to a paradigm shift in organic synthesis, relying on the selective activation of ubiquitous $\mathrm{C}-\mathrm{H}$ bonds in organic molecules instead of the standard approach of conducting transformations on preexisting functional groups. Since the first example of $\mathrm{C}-\mathrm{H}$ oxidative addition of benzene to a soluble transition metal complex was observed by Chatt and Davidson in 1965, ${ }^{14}$ the understanding and potential of $\mathrm{C}-\mathrm{H}$ activation reactions has been extensively studied. Throughout the 1980 's and into the 1990 's, a significant amount of research was focused on better understanding $\mathrm{C}-\mathrm{H}$ bond activation through investigations of intermediates, thermodynamics and kinetics, and selectivity of various stoichiometric reactions. These reactions further divided into two wide categories, direct $\mathrm{C}-\mathrm{H}$ activation reactions and directing group assisted $\mathrm{C}-\mathrm{H}$ activation reactions. ${ }^{15}$

### 3.1.2.1. Direct C-H Activation:

Reaction without directing group assistance refers to those where the $\mathrm{C}-\mathrm{H}$ bond is cleaved through direct metal insertion without the presence of heteroatoms for
metal chelation or to act as directing groups. The challenges of discriminating between various activation types of chemically similar $\mathrm{C}-\mathrm{H}$ bonds within the hydrocarbon skeleton and also regio selective $\mathrm{C}-\mathrm{H}$ activation remain to be addressed.

Scheme S3.3: Inter and Intramolecular palladium catalyzed direct $C-H$
The seminal work on direct $\mathrm{C}-\mathrm{H}$ activation reported by Fujiwara, address the effective metalation of aromatic $\mathrm{C}-\mathrm{H}$ bonds at room temperature using highlyelectrophilic, in situ generated, $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ cationic species in trifluoroacetic acid (TFA), leading to the regioselective inter- and intramolecular addition of simple arenes to C-C multiple bonds (Scheme S3.3). ${ }^{16}$ In most cases, the addition of alkynes exclusively affords the thermodynamically less stable cis-aryl alkene. The intramolecular hydroarylation of $\mathrm{C} \equiv \mathrm{C}$ bonds is facile and regiospecific because of the electrophilic metalation of aromatic $\mathrm{C}-\mathrm{H}$ bonds by the $\mathrm{Pd}(\mathrm{II})$ cationic species which is assisted by ethynyl coordination. In fact, this intramolecular reaction combines both chelation assistance and electrophilic metalation.

The next effective contribution for direct C-H activation was Milstein's Hecktype oxidative coupling reaction, which was found to be promoted by molecular oxygen, is one of the most remarkable examples of ruthenium catalyzed arene $\mathrm{C}-\mathrm{H}$ bond insertion reactions (Scheme S3.4). ${ }^{17}$ The catalytic oxidative coupling of arenes with alkenes to generate aryl alkenes, in which the double bond is preserved, is a highly desirable goal. Since the reaction does not require the utilization of reactive substituent and does not form any byproducts, it has a unique advantage over other methods for the preparation of aromatic alkenes, especially when compare to the wellknown Heck reaction for the vinylation of aryl halides. In Milstein's Heck type coupling, dioxygen can be directly used as the oxidant, while still retaining good catalytic activity. The reaction is catalyzed by ruthenium complexes under a CO atmosphere condition. Readily available ruthenium complexes such as $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$
(1), $\quad\left[\mathrm{Ru}(\mathrm{CO})_{3} \mathrm{Cl}_{2}\right]_{2}$ (2), $\quad\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2} \quad$ (3), $\quad \mathrm{Ru}(\mathrm{NO}) \mathrm{Cl}_{3} .5 \mathrm{H}_{2} \mathrm{O} \quad$ (4), and $\mathrm{Ru}\left(\mathrm{F}_{3} \mathrm{CCOCHCOCF}_{3}\right)_{3}(5)$ show essentially the same type of catalytic activity.

Scheme S3.4: Ruthenium catalyzed direct arene $C-H$ bond activation and functionalization with alkenes

Later Smith also described that iridium catalysts (MesH) $\operatorname{Ir}(\mathrm{BPin}) 3(\mathrm{MesH}=$ $\eta 6$-mesitylene, BPin $=$ oxaborolane) (6) were efficient for direct synthesis of arylboron compounds from aromatic hydrocarbons and boranes under "solvent-less" conditions (Scheme S3.5). ${ }^{18}$ The Ir catalysts are highly selective for $\mathrm{C}-\mathrm{H}$ bond activation and do not interfere with subsequent transformations, including Pdmediated cross-coupling with aryl halides. By virtue of their favorable activities and exceptional selectivities, these Ir catalysts impart the synthetic versatility of arylboron reagents to $\mathrm{C}-\mathrm{H}$ bonds both aromatic and heteroaromatic hydrocarbons.

Scheme S3.5: Iridium catalyzed boryllation of aromatic compounds by C-H activation

Smith proposed the reaction mechanism involving $\operatorname{Ir}(\mathrm{III})$ and $\operatorname{Ir}(\mathrm{V})$ intermediates as shown in Scheme S3.6. The following evidence supports the mechanism proposed in Scheme S3.6: (a) Borylation products of iodobenzene are not obtained when $\operatorname{Ir}(\mathrm{I})$ sources are used under stoichiometric or catalytic conditions, whereas $\operatorname{Ir}($ III $)$ complexes effect both stoichiometric and catalytic borylations. (b) Improved catalytic activity is observed with chelating phosphines and inhibition was observed when [phosphine]:[iridium] ratios equal or exceed $3: 1$, strongly supporting the viability of bisphosphine intermediates (Scheme S3.6, $\mathrm{n}=2$ ), which could be generated via $E-E$ reductive elimination $(E=H, B P i n)$ from an 18 electron
bisphosphine $\operatorname{Ir}(\mathrm{V})$ resting state. (c) The 18 electron bisphosphine compound, $\mathrm{IrH}_{5}\left(\mathrm{PMe}_{3}\right)_{2}$, is an efficient precatalyst for the borylation.

A

Scheme S3.6: Catalytic cycle for borylation

Hartwig discovered a highly selective, acceptor-less dehydrogenative coupling of silanes with arene $\mathrm{C}-\mathrm{H}$ bonds in good yields in the presence of TpMe 2 PtMe 2 H ( $\mathrm{TpMe}_{2}=$ hydridotris(3,5-dimethylpyrazolyl)borate) and related platinum(IV) complexes (Scheme S3.7). ${ }^{19}$ The reaction of the arenes occurred selectively at the least sterically hindered $\mathrm{C}-\mathrm{H}$ bonds and preferentially with more electron-poor arenes. If the dehydrogenative coupling of simple silanes with aromatic and aliphatic C-H bonds could be developed, then useful reactions could result. Because of the higher stability of silanes toward disproportionation than boranes, they could undergo tandem or sequential reactions that would be impossible using borane or even disilane reagents.

Scheme S3.7: Platinum catalyzed direct $C$-H activation

### 3.1.2.2. Chelation Assisted C-H functionalization

The directed or chelation assisted $\mathrm{C}-\mathrm{H}$ activation, the reaction facile through the metal chelation with heteroatom. In the area of $\mathrm{C}-\mathrm{H}$ bond functionalization chemistry, the directed or chelation assisted $\mathrm{C}-\mathrm{H}$ bond activation reactions with some of the transition metal catalysts were found to be very efficient tools for their substrate tolerance of functional groups and wide range of synthetic utility. ${ }^{11 b, 20}$

Figure S3.1: schematic representation of chelation assisted C-H activation
Over the past decade, chelation-controlled (functional group directed) $\mathrm{C}-\mathrm{H}$ bond activation reactions by various transition metal catalysts have been reported by many research groups using directing (functional) group containing arenes and heteroarenes. Two mechanistically distinct reaction pathways are now proposed with modes of $\mathrm{C}-\mathrm{H}$ bond activation by metal (Figure S3.1).

First of all, the heteroatom could be used as a chelating group to bind the metal catalyst, facilitating reactivity at the substrate ortho position. In this case, the formation of the heterometallacycle with oxygen or nitrogen provides a favorable driving force inducing regiochemistry. In the case of heteroatom initially coordinates to the metal center, acts to stabilizes the formation of a metal-carbon bond using a proximal $\mathrm{C}-\mathrm{H}$ bond from the substrate and then the functionalization occurs.

s7.A

S7.C

Figure S3.2: Types of chelation assisted $C-H$ activation
The use of chelation control in $\mathrm{C}-\mathrm{H}$ bond functionalization offers several advantages with respect to substrate scope and application to total synthesis. Pioneering work in this field such as rhodium-catalyzed $\mathrm{C}-\mathrm{H}$ alkylation was
developed by Lim and Kang using pyridine as the directing group. More recently, imine functional groups have been employed in the $\mathrm{C}-\mathrm{H}$ bond alkylation using $\mathrm{Rh}(\mathrm{I})$ catalysts. In addition, the limited scope of intermolecular hydroarylation due to olefin isomerization leads to research on intramolecular $\mathrm{C}-\mathrm{H}$ alkylation reactions. These alkylation methods were applied in natural products synthesis like mescaline and (+)lithospermic acid. While the hydroarylation of olefins showed great success in organic chemistry, research into Rh-catalyzed alkenylation and annulations has been examined by only a few chemists. In most cases, $N$-directed alkenylation was commonly used with alkyne derivatives, whereas $N$-benzyl chelating groups afforded annulation products with phenylacetylenes under higher temperature and at prolonged reaction times. The development of $\mathrm{C}-\mathrm{H}$ arylation reactions is now another subject of active investigation that can be addressed by Rh compounds. Various aryl sources have been employed in $\mathrm{C}-\mathrm{H}$ arylation reactions, despite the production of unwanted di-arylation side product. Additionally, the carbonylation reactions were also reported using chelation-assisted arenes and CO as the carbonyl source. Unfortunately, a limited substrate scope only was possible because of harsh reaction conditions that degrade certain functionalization.

An alternative method for achieving selectivity in $\mathrm{C}-\mathrm{H}$ bond functionalization is to apply an electronic stabilizing group which makes metal-carbon bond at proximal site on compounds easily. This approach has been previously utilized in the Rh-catalyzed alkylation and arylation. The initial approach of azole reactions using Rh catalysts were reported by Ellman and Bergman. Both intramolecular and intermolecular versions of alkylation reactions have been researched that involve a wide scope of substrates. Although, high temperature was needed in this transformation, heterocycles including pyridines and azolines were activated by this method. Additionally, the fascinating mode of activation and excellent functional group tolerance that Rh catalysts offer, led to arylation reactions with various azoles. Azoles as well as arenes with a single heteroatom also were activated by rhodium to yield functionalized products. ${ }^{22}$

The unique reactivity of rhodium catalyst leads to a new avenue for $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{N}$ bond formation. This system shows high regioselectivity with a broad substrate scope. Owing to high functional group tolerance, both chelation-assisted and heteroatom-directed $\mathrm{C}-\mathrm{H}$ bond functionalization have been employed in the synthesis of complex molecules.

Murai pioneered chelate-assisted, regioselective, catalytic $\mathrm{C}-\mathrm{H}$ bond activation of arene and olefin coupling reaction. For example, acetophenone was added to vinyl silane to yield regioselectively alkylated product at the ortho position (Scheme S3.8). ${ }^{23}$ The ruthenium complex $\mathrm{RuH}_{2}(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{3}(7)$ was found to be an efficient catalyst for this coupling reaction. This reaction is a quite effective synthetic method, and, in many cases, gave nearly quantitative yields.

Scheme S3.8: [Ru] catalyzed C-H functionalization with vinylsilanes

As shown Scheme S3.9, Murai proposed that the reaction involves the coordination of the carbonyl group of aryl ketones to the ruthenium center and is placed in a favorable position for the cleavage of the $\mathrm{C}-\mathrm{H}$ bond. The ruthenium hydride complex $\mathbf{8}$ has been suggested as a key intermediate species. The rate-limiting step of the coupling reaction is the $\mathrm{C}-\mathrm{C}$ bond forming step instead of $\mathrm{C}-\mathrm{H}$ activation step. ${ }^{23}$

Scheme S3.9: Catalytic cycle for [Ru] catalyzed heteroatom directed $C-H$ activation
The reaction was extended to various arene and olefin coupling reactions. One of the most important findings in elucidation of the mechanism of coupling reaction is that the $\mathrm{C}-\mathrm{H}$ bond cleavage step is not the rate-limiting step. Instead a rapid equilibrium exists prior to the reductive elimination step that leads to the $\mathrm{C}-\mathrm{C}$ bond formation. Murai has established that the reductive elimination of alkylated products is the rate-determining step.

The rhodium bis-olefin complex $\left[\mathrm{Cp} * \mathrm{Rh}\left(\mathrm{CH}_{2}=\mathrm{CHSiMe}_{3}\right)_{2}\right]$ (9) has also been shown to be an effective catalyst for selective addition of olefins to the ortho position of arylketones (Scheme S3.10). A main difference between scheme S3.8 and scheme S3.10 is that in the ruthenium catalyzed process, carbonyl coordination is presumed to be the first step, which directs the $\mathrm{C}-\mathrm{H}$ bond activation to the ortho position of the aromatic substrate.

Scheme S3.10: [Rh] catalyzed C-H functionalization with vinylsilanes
$\mathrm{H} / \mathrm{D}$ exchange experiments established that para and meta $\mathrm{C}-\mathrm{H}$ bonds are not activated in the ruthenium system. The rhodium catalytic processes, on the other hand, are not discriminating in the $\mathrm{C}-\mathrm{H}$ bond activation step and activation of all sites (ortho, meta, and para) of the substrate ws observed. Murai has established that the $\mathrm{C}-\mathrm{H}$ bond activation is fast and reversible in the ruthenium case and reductive elimination of the alkylated product is the rate-limiting step. It is believed that the similar features are applied to the rhodium system as well, but no conclusive evidence is available concerning this point. In the both systems, the energy barrier for reductive elimination which then forms the product is decreased by chelation of the carbonyl group to the metal center.

### 3.1.2.3. C-H Activation and Branched Selective Alkylations:

The branched selective hydroarylation via $\mathrm{C}-\mathrm{H}$ activation is one of the demanding tasks till date. Reports are available in literature, wherein, when styrene was employed an olefin counterpart in Murai reaction, the formation of the branched selective alkylation has been noticed (Scheme S3.11). ${ }^{24}$ Use of bulky phospines as additives has increased the linear selectivity. Despite its occurrence, there has been little attention paid on the possibility of branched-selective alkylation until recently.

Scheme S3.11: [Ru] catalyzed C-H functionalization with styrene

In 2009, Takai et al. reported the Rhenium catalyzed branched selective alkylation of phenol, which is the first report with phenolic hydroxy has a directing group. ${ }^{25}$ The paromount importance in this methodology was regioselective introduction of long chain olefins at the ortho or para position of hydroxyl group selectively with $\operatorname{Re}_{2}(\mathrm{CO})_{10}$ complex (Scheme S3.12). Some of the selected rhenium complexes were screened, but among them $\mathrm{Re}_{2}(\mathrm{CO})_{10}$ showed better activity and excelent selectivity. The scope and limitations of phenol derivatives with 1-octene were investigated in toluene at $135^{\circ} \mathrm{C}$ and also scope of aliphatic olefins examined, in which ortho or para and some cases both ortho and para alkylated mixture were also observed.

Scheme S3.12: [Re] catalyzed $C-H$ functionalization with olefines
Shibata et al reported the Iridium catalyzed C2-alkylation of $N$-substituted indole derivatives with various alkene with a remarkable linear or branched selectivities. ${ }^{26}$ This protocol relies on the use of the carbonyl group on the nitrogen atom of indole as a directing group, a linear product was predominant when an acetyl group was used as a directing group, and a branched product was predominant with a benzoyl group. The selectivity of linear or branched product was controlled by the directing group and ligand (Scheme S3.13). Albeit the results provided on regioselective hydroarylation of olefines using indoles are path breaking, however, the details on factors behind this unusual activity and how the directing group and ligand tuned the same, have been not yet addressed.

Scheme S3.13: [Ir] catalyzed regioselective alkylation with olefines
Very recently kanai et al reported the cobalt catalyzed C4- alkylation of pyridines with excellent linear or branched selectivity depending upon the nature of the olefine employed. A new hypothesis based on catalytic nucleophilic addition/rearomatization has been executed. ${ }^{27}$ A catalytic amount of $\mathrm{CoBr}_{2}$ in combination with $\mathrm{LiBEt}_{3} \mathrm{H}$ gave branched adducts from styrene derivatives, and linear
adducts from aliphatic alkenes. As shown in Scheme xx, the reaction proceeds via hydrometalation of alkenes and subsequent nucleophilic addition of the resulting alkyl-metal species to pyridine C 4 affords a dihydropyridine intermediate. The rearomatization of pyridine leads to the regeneration of the metalhydride catalyst. The high catalyst turnover numbers (up to $3440 ; \mathrm{s} / \mathrm{c}=4000$ ) observed in the reaction with styrene are noteworthy. However, the mechanistic studies also couldn't make any clear evidance on the variation on the mode of alkylation with styrene and aliphatic 1alkene.

Scheme S3.14: [Co] catalyzed regioselective alkylation with styrene
Yoshikai et al developed the concept of regioselective hydroarylation switch by using low valent cobalt catalysis. The investigation commenced the development of chelation assisted hydroarylation reactions of styrenes particularly. The beauty of this concept is ligand-controlled regioselectivity switch and the study of orthogonal scope and selectivity of the Lewis acid. This low valent metal catalyzed hydroarylation reactions, in particular, the branched selectivity hydroarylation with the $\mathrm{Co}-\mathrm{PCy}_{3}$ catalysis is highly attractive. Their inaguaral application on this concept was delivared with pyridine directed regioselective hydroarylation with $\mathrm{CoBr}_{2}$ and $\mathrm{Me}_{3} \mathrm{SiCH}_{2} \mathrm{MgBr}, \mathrm{PCy}_{3}$ ligand has used for tuning the branched selective alkylation and IMes $\cdot \mathrm{HCl}$ has been used for tuning the linear selective alkylation. ${ }^{28}$ This seminal contribution later taken forward with aldamine nitrogen directed branched selective alkylation on napthyl ring with styrene derivatives ${ }^{29}$ and it was followed by the intramolecular aldamine nitrogen directed branched selective C2-alkylation on indole moiety. ${ }^{30}$ In this case the regioselectivity of the cyclization reaction is primarily dependent on the structure of the olefin tether, but is controllable by the steric nature of the NHC ligand when the tether is a parent homoallyl group, which is an example
of catalytic regiodivergent synthesis. The results were summerized in scheme, SIMes $\cdot \mathrm{HCl}$ was identified as a promising pre-ligand, affording the expected cyclization products $\mathbf{S 1 4 H}$ and $\mathbf{S 1 4 I}$ with a ratio of 4:1.

Scheme S3.15: [Co] catalyzed regioselective alkylation with olefines

### 3.1.3. Metal catalyzed coupling of acrylates:

Acrylates are esters of acrylic acids. They are also known as propenoates, they contains vinyl groups, that is, two carbon atoms double bonded to each other, directly attached to the carbonyl carbon.

Figure S3.3: Resonance structures of acrylates
The conjugation of alkene with the carbonyl group provides special properties. The carbonyl group draws electrons away from the alkene, and the alkene group is, therefore, deactivated towards an electrophile. These compounds are activated towards nucleophiles for conjugate additions. The involvement of acrylates as
coupling partners/electrophiles in the $\mathrm{C}-\mathrm{H}$ activation reactions can be divided in to two types:
i. alkenylation (cross dehydrogenative coupling)
ii. alkylation (Murai reaction)

### 3.1.3.1. Cross Dehydrogenative Coupling (Alkenylation) of Acrylate via C-H activation

Carretero et al reported the $\mathrm{Pd}(\mathrm{OAc})_{2}$ catalyzed, sulfonyl group directed ortho alkenylation with acrylates on N -alkyl N -(2-pyridyl)sulfonyl anilines and arylalkylamines and also extended the $\mathrm{C}-\mathrm{H}$ functionalization to di ortho olefination on carbzole (Scheme S3.16). ${ }^{31}$

Scheme S3.16: [Pd] catalyzed sulfonyl directed alkenylation with olefines
Oestreich et al has documented recently $\mathrm{Pd}(\mathrm{OAc})_{2}$ catalyzed, $\mathrm{C}-7$ selective $\mathrm{C}-$ H bond alkenylation of indolines. BQ was used as oxidant, but it was also possible to perform the cross coupling under aerobic conditions, infrequently used urea has been utilized as directing group and good to excellent yield was obtained (Scheme S3.17). ${ }^{32}$ Yu and other groups ${ }^{32 \mathrm{~b}}$ also benefited to achieve the alkenylation by utilizing urea as directiong group.

Scheme S3.17: [Pd] catalyzed urea directed alkenylation with olefins
Zhang et al reported the $\mathrm{Pd}(\mathrm{OAc})_{2}$ catalyzed direct $\mathrm{C}-\mathrm{H}$ bond functionalization strategy for the olefination of polyfluoroarenes, which represents one of the rare examples of catalytic direct olefination of electron-deficient arenes. This transformation has been promoted by thioether (PhSMe) (Scheme S3.18). They
have demonstrated the power of the new ligand PhSMe , has shown the reaction of those previous 'inert' substrates to provide high yields. ${ }^{33}$

Scheme S3.18: [Pd] catalyzed alkenylation with olefins
Zhu et al established a novel and general method for the synthesis of 4-alkenyl-2oxazolones featuring the first Pd catalyzed direct $\mathrm{C}-\mathrm{H}$ activation and functionalization on 2-oxazolones and $\mathrm{Cu}(\mathrm{OAc})_{2}$ used as oxidant to promote the reaction (Scheme S3.19). ${ }^{34}$

Scheme S3.19: [Pd] catalyzed alkenylation with olefins

The first examples on the use of Ru-complexes for the carbonyl directed dehydrogenative cross coupling reaction with acrylates has been reported by Miura in 2009 employing heterocyclic systems such as benzofuran and indole derivatives (Scheme S3.20). ${ }^{35}$

Scheme S3.20: [Ru] catalyzed alkenylation with olefins
The employed conditions involve the use of $\mathrm{Ru}(p$-cymene $) \mathrm{Cl}_{2}$ as a catalyst and $\mathrm{Cu}(\mathrm{OAc})_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ oxidant. This initial success with Ru -complexes has been later well explored by various other systems and with diverse directing groups mainly by Ackemann and Jeganmohan groups. Wang, Ackermann and Jeganmohan independently reported Ru catalyzed phenol carbamate directed ortho alkenylation (Scheme S3.21). ${ }^{36}$ Advantage from this intial success, later they have independently reported Ru catalyzed ester directed ortho alkenylation on arenes ${ }^{37}$ followed by

Jeganmohan's Ru catalyzed aldehyde directed ortho alkenylation on arenes ${ }^{38}$ is a noteworthy example.

Scheme S3.21: [Ru] catalyzed carbonyl directed alkenylation with olefins

Glorius et al documented very recently, Rh catalyzed phosphonate and phosphonamide directed $\mathrm{C}-\mathrm{H}$ activation for alkenylation of arylphosphonates and phosphonamides at ortho position. The cationic rhodium species $\mathrm{RhCp} *\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}\left(\mathrm{SbF}_{6}\right)_{2}$ successfully catalyzed when $\mathrm{Cu}(\mathrm{OAc})_{2}$ used as oxident in DCE under air at $130{ }^{\circ} \mathrm{C}$ for 24 h and furnished good to excellent yields (Scheme S3.22). ${ }^{39}$

Scheme S3.22: [Rh] catalyzed directed alkenylation with olefins

Antonchick et al reported recently Rh catalyzed, regioselective C-7 C-H bond alkenylation of indulines by using infrequently used urea as a directing group. This has achieved after Oestreich's contribution with $\mathrm{Pd}(\mathrm{OAc})_{2} . \mathrm{Cu}(\mathrm{OAc})_{2}$ was used as oxidant instead of BQ with cataionic $\left[\mathrm{RhCp}^{*}\left(\mathrm{SbF}_{6}\right)\right]_{2}$, to furnish the excellent yields of olefination (Scheme S3.23). ${ }^{40}$

Scheme S3.23: [Rh] catalyzed directed alkenylation with olefins

Prabhu et al recently documented the Ru catalyzed a selective C2-alkenylation of indole using carbonyl oxygen as a directing group and C4-alkenylation also reported via the $\mathrm{C}-\mathrm{H}$ functionalization using carbonyl oxygen of an aldehyde as a directing group (Scheme S3.24). ${ }^{41}$

Scheme S3.24: [Ru] catalyzed directed alkenylation with olefins

Takai et al reported the Re catalyzed pyridine directed acrylate insertion into an Aromatic C-H Bond at the ortho position of a directing group (Scheme S3.25). ${ }^{42}$

Scheme S3.25: [Re] catalyzed directed alkenylation with olefins
Unlike the cross dehydrogenative coupling, the alkylation with acrylates inter alia the use of acrylates in the Murai reaction have been less explored.

Scheme S3.26: [Rh] catalyzed directed alkenylation with olefins

In the initial disclosures, Murai has attempted the use of acrylates as coupling partners employing the dihydropyran derivatives, unlike the simple olefins where excellent yields are obtained, with methyl methacrylate, the product was formed in very poor yields. This observation with acrylates has been taken granted in general that they are poor substrates in Murai reaction (Scheme S3.26). ${ }^{43}$

However, recently, Jun and Takai independently reported the Rh and Re catalyzed imene directed ortho hydroarylation with acrylates (Scheme S3.27). ${ }^{44}$

Scheme S3.27: [Rh] catalyzed directed alkenylation with olefins
Very reacently, while our work was in progress, Chatani and co-workers reported the first successfull Ru-catalyzed Murai reaction with enone systems. ${ }^{45}$

From the examples given above it is evident that the Murai reaction with acrylates has been yet to addressed. Another interesting observation is, either in the classical cross-coupoing reactions or in the cross dehydrogenative couplings, when acrylates employed as the electrophiles, in general, linear products are observed exclusively. Only, in 2011, the first example on the regio-irregular coupling with acrylates has been documented by Wucher and co-workers in the Mizoroki-Heck coupling reaction. However, the Pd-complex was used in stoichiometric amounts. ${ }^{46}$

Wucher and coworkers reported the remarkable strategy for the carbon-carbon bond formation. The authors illustrated the results by reinventing the regioselective rule in the Mizoroki-Heck coupling, which is the most prominent example in organic synthesis and also by catalytic insertion polymerization. Usually electron-deficient olefins insert selectively 2,1 fashion for electronic reasons. The The authors have commenced the regioselective insertion of acrylate by destabilizing the transition state of 2,1-insertion via steric interactions, the regioselectivity of methyl acrylate insertion into palladium-methyl and phenyl bonds can be inverted entirely to yield the opposite "regioirregular" products in stoichiometric reactions. Insights from these experiments will aid the rational design of complexes which enable a catalytic and regioirregular Mizoroki-Heck reaction of electron-deficient olefins (Scheme S3.28).

Scheme S3.28: [Pd] catalyzed regioselective acrylate insertion

The concept which allows reversal of the commonly valid regioselectivity rule for the insertion of the electron-deficient olefin MA into palladium carbon bonds. Appropriately arranged steric bulk of the ligands bound to the palladium center results in a severe steric repulsion with the incoming substrate in the electronically favored 2,1-insertion transition states. This steric repulsion makes the less sterically encumbered 1,2 -insertion transition states competitive and strongly favored, thus overriding the usual distinct electronic determination of the insertion reaction. But they used bulky phosphine ligands and the palladium complex used in stoichiometric ratio. However this results certainly aid the rational design of catalysts that provide selective access to a catalytic regioirregular Mizoroki-Heck reaction.

## Introduction

Benzofuran is one of the commonly encountered structural units in natural products as well as in medicinally important small molecules. The 2,3-disubstituted benzofurans deserves a special mention as they have served as building blocks for a number of natural products synthesis and possess unique biological activities. For example, the 2-(2-aroylbenzofuran-3yl)acetates (Type I); 3-(2-aroylbenzofuran-3-yl)propanoates (Type II) and their regiomeric counterparts (Types III and IV respectively, Fig.3.1) have been identified as novel antiinflammatory agents and Antiarrhythmic agents respectively. ${ }^{47}$ The compounds of Type I are known to inhibit the type IV phosphodiesterase, which results in the elevation of cellular cAMP that regulate the production of superoxide by polymorphonuclear leukocytes (PMN). ${ }^{48}$

Figure 3.1: Structures of selected drugs/investigational drugs having the 2,3-disubstituted benzofuran core and classification of the 2-/3-aroylbenzofuran class of molecules

The reported procedure for the synthesis of these compounds is multistep in nature and involves harsh reaction conditions such as Fridel-Crafts acylation and acid/base mediated condensations. ${ }^{49} \mathrm{~A}$ plausible approach will be the one-pot sequential metal-catalyzed cyclization of 2-alkynylphenols followed by the trapping of the intermediate aryl metal species with $\alpha, \beta$-unsaturated carbonyl compounds. In 2009, two research groups (Aurrecoechea and Lautens) independently reported the [Pd] and [Rh]-catalyzed tandem cyclization cum Heck-type coupling between 2-alkynylphenols and alkenes, which led to 2,3-disubsitutedbenzofurans (Scheme 3.1). ${ }^{50}$ In both the cases, the reaction proceeds via the
cyclization of 2-alkynylphenols and subsequent trapping of the intermediate benzo[b]furanyl-C3-metal species with $\alpha, \beta$-unsaturated carbonyl compounds. However, substituents at the C2 are limited mainly to the alkyl or aryl group and $\beta$-substituted acrylates found as poor substrates.

Scheme 3.1: Reported Rh-/Pd-catalyzed cyclization-conjugate addition cascade
In 2011, Satoh, Miura and co-workers reported a complementary method for this purpose that involves the C2 carboxylate directed cross-dehydrogenative coupling of alkyl acrylates and benzo[b]furan-2carboxylate derivatives (Scheme-S3.20). ${ }^{35}$ The cheap and inexpensive $\left[\mathrm{RuCl}_{2}(\mathrm{p} \text {-cymene })\right]_{2}$ has been employed as the catalyst and $\mathrm{Cu}(\mathrm{OAc})_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ as the stoichiometric oxidant. The reactions proceeded with complete linear selective alkenylation. As mentioned in the introduction, this initial success with ruthenium (II)-mediated cross dehydrogenative couplings has been explored further by several other groups employing a wide range of directing groups on both aryl and heteroaryl rings. The recent report of the Pdcatalyzed C3 arylation of 1-aroyl benzofuran derivatives by Bertounesque and co-workers needs a special mention here. ${ }^{51}$

Scheme S3.20: Miura's landmark aproach on first Ru-catalyzed cross- dehydrogenative coupling
Given the biological significance of the compounds of Type I-IV, and the presence of a weak coordinating group such as aroyl on the benzofuran ring, the $\mathrm{C}-\mathrm{H}$ elaboration of activation methods for these heterocycles will be a suitable facile alternative for the synthesis of these important pharmaceuticals. We have been interested in exploring the possibility of
the C2-carbonyl directed C 3 alkylation of benzo $[b]$ furans using the $\alpha, \beta$-unsaturated carbonyl compounds as electrophiles. Needless to say that with $\alpha, \beta$-unsaturated esters (acrylates) it is still a big challenge to do regioselective hydroarylation on aryl or heteroaryl groups with any metal catalyst. Many endeavours end up with only dehydroarylation (alkenylation) and very few reports deal with Rh and Re providinglinear alkylation. ${ }^{44,}{ }^{42}$ There have been strong debates on commonalities and differences of the directing group influence on the outcome of the reaction and the elaboration of its mechanistic studies. However the investigations have been limited.

Figure 3.2: $C-H$ activation approach for the requisite branched/linear alkylation on benzofurans
Figure 3.2 reveals our intended strategy for the synthesis of 3-substituted 2aroylbenzofurans of Type II derivatives via carbonyl directed $\mathrm{C}-\mathrm{H}$ activation. Considering the fact that the earlier reports on similar reactions in general employ re-oxidants such as $\mathrm{Cu}(\mathrm{OAc})_{2}$ for cross-dehydrogenative coupling, ${ }^{37,38}$ we intended to explore the possibility of alkylation with acrylates without using any such oxidant. Since cationic Ru-arene complexes have been employed for the cross dehydrogenative couplings, our concern was whether the neutral ruthenium-complexes will pave the path for the alkylation with acrylates.

Scheme 3.2: Synthesis of 2-aroylabenzofuran substrates
The starting 2-aroylbenzofuran derivatives 20a-20e have been synthesized by following the established procedures. ${ }^{52}$ As shown in Scheme 3.2, the synthesis involves the
treatment of a salsiladehyde derivative with 2-bromo acetophenonein the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ in acetone for 3 h at its reflux temparature.

After having a diverse set of substrates, the initial studies began with the identification of the optimal catalyst for the requisite alkylation with methyl acrylate. Some selected ruthenium complexes have been screened as catalysts for this purpose using benzo[b]furan 20a as the substrate and methyl acrylate 21a as an acceptor and the conditions used were those that have been commonly prescribed for the directed $\mathrm{C}-\mathrm{H}$ bond activations (Table 3.1). The employed conditions in the exploratory experiments involved the heating of a mixture of $\mathbf{2 0 a}$ with excess acrylate ( 3 eq .) in the presence of the catalyst ( $10 \mathrm{~mol} \%$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$ ( 3.0 eq .) and adamantane-1-carboxylic acid $\left(\mathrm{AdCO}_{2} \mathrm{H}, 0.3\right.$ eq.) in toluene at $140{ }^{\circ} \mathrm{C}$ for 12 h in a screw-capped sealed tube. These preliminary experiments revealed that the desired alkylation of 20a was viable. Quite interestingly, the formation of substantial amounts of branched alkylated products 22aa along with the linear product 23aawas noticed. The ratio of linear vs branched products seems to be catalyst dependent. Among the various ruthenium complexes screened, the best branched selectivity was obtained with $\mathrm{Ru}_{3}(\mathrm{CO})_{12}, \mathrm{RuH}_{2}(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{3}$ and $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$. The results have been summarized in table 3.1.

Table 3.1.Catalyst screening for directed hydroarylation

| S.No | Catalyst | Yield (\%) ${ }^{\text {a }}$ (22aa/23aa) |
| :---: | :--- | :---: |
| 1 | $\left[\mathrm{Ru}(p \text {-cymene }) \mathrm{Cl}_{2}\right]_{2}$ | $23(28 / 72)$ |
| 2 | $\mathrm{Ru}_{3}(\mathrm{CO})_{12}$ | $31(83 / 17)$ |
| 3 | $\mathrm{RuCl}_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ | nd |
| 4 | $\mathrm{RuO}_{2}$ | No reaction |
| 5 | $\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Ru}(\mathrm{CO}) \mathrm{H}_{2}$ | $73(89 / 11)$ |
| 6 | ${\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}}^{\text {a }}$ isolated yield; $\mathrm{nd}=$ not determined (complex reaction mixture) |  |

The products were confirmed by NMR and HRMS. In the ${ }^{1} \mathrm{H}$ NMR spectrum the branched alkylated product 22aa, the $\mathrm{C}^{\prime}{ }^{\prime}-\mathrm{H}$ and $\mathrm{C}^{\prime}{ }^{\prime}-\mathrm{H}$ were seen to resonate at $\delta 8.10-8.16$ ppm as a multiplet and the characteristic benzofuran $\mathrm{C} 3-\mathrm{H}$ was seen to disappeared.The
methoxy group of thepropionate unit resonated at $\delta 3.68 \mathrm{ppm}$ as a singlet andthe terminal methyl group at $\delta 1.67 \mathrm{ppm}$ as doublet with $J=7.2 \mathrm{~Hz}$ and methyne $(\mathrm{CH})$ at $\delta 4.96 \mathrm{ppm}$ resonated as quartet with $J=7.2 \mathrm{~Hz}$. In the ${ }^{13} \mathrm{C}$ NMR spectrum of compound 22aa, the characteristic benzofuran C3 carbon appeared as a singletat $\delta 126.7 \mathrm{ppm}$ and the corresponding propionate methoxy carbon resonated at 52.2 ppm as a quartet. The terminal methyl carbon resonated at 16.8 ppm as quartet, the methyne $(\mathrm{CH})$ carbon at $\delta 35.9$ as a doublet and the carbonyl carbon resonated at $\delta 185.9 \mathrm{ppm}$ as a singlet. In the HRMS, the exact mass of the compound showed, as calculated, for $\mathrm{C}_{19} \mathrm{H}_{16} \mathrm{O}_{4} \mathrm{Na}\left(\mathrm{M}^{+}+\mathrm{Na}\right): 331.0941$ and it was found to be 331.0938. Considerations of the cost, stability and the good yield obtained, when compared with $\mathrm{Ru}_{3}(\mathrm{CO})_{12}$ and $\mathrm{RuH}_{2}(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{3}$, led us to select the $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ complex for further optimization studies.

${ }^{\text {a }}$ Reaction conditions: benzofuran ( 1 eq .), methylacrylate (3 equiv), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ catalyst ( 10 $\mathrm{mol} \%$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$ (unless otherwise mentioned, 3 equivalents with respect to 20), Additive ( 30 $\mathrm{mol} \%$ ), $140{ }^{\circ} \mathrm{C}$, solvent, $24 \mathrm{~h} ;{ }^{\mathrm{b}}$ isolated yield after column chromatographic purification; ${ }^{\mathrm{c}}$ clean reaction; ${ }^{\mathrm{d}}$ intractable compounds increased in the reaction mixture; ${ }^{\mathrm{e}}$ recovered unreacted starting material; ${ }^{\text {f }}$ keto group was reduced; nd $=$ not determined (complex reaction mixture); $\mathrm{NR}=$ no reaction.

The optimization experiments were carried out for improving the yield and regio selectivity by using $5 \mathrm{~mol} \%$ catalyst, 3 equivalents of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and $30 \mathrm{~mol} \%$ of additive. Various additives have been used (entries 1-5, Table 3.2), Silver acetate has been found to be the best additive for improving the selectivity and consequently, the products were isolated in excellent yield. Coming to the solvents screened, DMSO (Entry 7), DMF (Entry 8) and DCE (Entry 9) were found to be completely ineffective. Reduction of the keto group was observed when NMP was used as the solvent (Entry 10). ${ }^{53}$ In 1,4-dioxane, the reaction gave good yield, but the selectivity was reduced (Entry 11), Thus, toluene has been identified as the solvent of choice for which both the yield and the selectivity were found to be the best. Control experiments revealed that the reaction also proceeds without AgOAc (entry 12, Table 3.2), but with a high increase in the amount of intractable compounds in the mixture. Experiments with varying concentrations of $\mathrm{K}_{2} \mathrm{CO}_{3}$ revealed that its presence is essential (entries 12-15, Table 3.2).

${ }^{\mathrm{a}}$ Reaction conditions: benzofuran (1 equiv), acrylate (3 equiv), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(5$ $\mathrm{mol} \%$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$ (3equiv), $\mathrm{AgOAc}\left(30 \mathrm{~mol} \%\right.$ ), $140{ }^{\circ} \mathrm{C}$, toluene, 24 h . ${ }^{\mathrm{b}}$ isolated yield after column chromatographic purification. The ratio has been confirmed by HPLC and ${ }^{1} \mathrm{H}$ NMR.

The compatibility of various $\alpha, \beta$-unsaturated esters as coupling partners has been explored under the optimized conditions employing $\mathbf{2 0 a}$ as the substrate. The reaction of $\mathbf{2 0 a}$ with ethyl-, butyl-, and cyclohexyl acrylates (21b-21d) gave the corresponding products in
very good isolated yields without substantial difference in the branched/linear selectivity. In case of methyl crotonate (21e), the reaction proceeded smoothly and the corresponding branched adduct 22ae was obtained as the major product and the 1,5 -addition linear adduct was obtained as the minor isomer (24) with an overall yield of $84 \%{ }^{44}$ The minor isomer (24) has been confirmed by NMR and HRMS (see the experimental section). In the ${ }^{1} \mathrm{H}$ NMR spectrum of the linear alkylated product 24, the protons of threemethylenes $\left(\mathrm{CH}_{2}\right)$ were resonated at $\delta 2.12 \mathrm{ppm}$ as quintate $(J=7.5 \mathrm{~Hz}, 2 \mathrm{H}), 2.46 \mathrm{ppm}$ as triplet $(J=7.5 \mathrm{~Hz}, 2 \mathrm{H})$, 3.22 ppm as triplet $(J=7.6 \mathrm{~Hz}, 2 \mathrm{H})$. In the ${ }^{13} \mathrm{C}$ NMR spectrum these three methylene carbons were appeared as triplets at $\delta 23.7,24.7$ and 33.5 ppm . However, with both methyl- and butyl methacrylates ( $\mathbf{2 1 g}$ and 21h), the corresponding linear adducts 23ag and 23ah were formed as the only products.This result indicates that steric factors might be playing a substantial role in deciding the linear vs branched selectivity. In the case of ethyl cinnamate (21f), the reaction was sluggish and the branched adduct 22af was obtained as the major product in moderate yield/conversion (Table 3.3).

Table 3.4: Acrylate scope and structural variations to the benzofuran counterpart.

${ }^{\mathrm{a}}$ Reaction conditions: benzofuran ( 1 equiv), acrylate (3 equiv), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}\left(5 \mathrm{~mol} \%\right.$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$ (3equiv), $\mathrm{AgOAc}(30 \mathrm{~mol} \%), 140^{\circ} \mathrm{C}$, toluene, 24 h . ${ }^{\text {b }}$ isolated yield after column chromatographic purification. ${ }^{\mathrm{c}}$ recovered unreacted starting material. nd $=$ not determined (complex reaction mixture).

The generality of the branched selective alkylation with 21a, 21b and 21e has been examined further by employing variously substituted 2-aroylbenzofurans 20b-20e, and all the reactions were seen to be facile with the optimized conditions and furnished excellent yield. As indicated in Table 3.4, the presence of the electron withdrawing group on the phenyl ring led to the increase in the linear product formation. On the other hand, the presence of the electron donating groups on the phenyl ring enhanced the branched selectivity. The presence of the electron withdrawing substituent on the benzofuran ring has, at most, only nominal influence on the selectivity. Interestingly, when a methyl group is present in place of chlorine, the selectivity was found to drop slightly. These observations indicate that the coordinating ability of the carbonyl group with the metal center has some influence on the branched $v s$ linear selectivity.

Next, in order to learn about the role of the directing group, the reaction has been conducted with different C 2 substituted benzofuran derivatives (Scheme 3.3). As expected, both 2-alkyl-, 2-phenyl and 2-carboxylate derivatives were intact under these conditions. In case of 2-acetyl benzofuran, the reaction proceeded smoothly, with the product formation occurring in good yield. However, the regioselectivity dropped to $\sim 1: 1$. Very interestingly, in case of benzofuran-2-yl(phenyl)methanol, both the oxidation and alkylation are facile and resulted in 22aa.

Scheme 3.3: Scope of directing groups ${ }^{\mathrm{a}, \mathrm{b}}$

${ }^{\mathrm{a}}$ Reaction conditions: $20(1 \mathrm{mmol}), 21(3 \mathrm{mmol}), \mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(5 \mathrm{~mol} \%), \mathrm{K}_{2} \mathrm{CO}_{3}(3$ mmol ), $\mathrm{AgOAc}\left(30 \mathrm{~mol} \%\right.$ ); ${ }^{\text {b }}$ isolated yield and ratio determined by ${ }^{1} \mathrm{H}$ NMR

These observations clearly reveal the necessity of a carbonyl group for the desired alkylation and the steric influence of the pendant alkyl/aryl group on regioselectivity. Later, we have examined the scope of this reaction with respect to the substituents on alkene by employing $N$-isopropylacrylamide, acrylonitrile, methylvinyl ketone, styrene and dodecene as representative olefin partners and 2-benzoylbenzofuran (20a) as a substrate (Scheme 3.4).

Scheme 3.4: Scope of olefin partners ${ }^{\text {a }}$

${ }^{\mathrm{a}}$ Reaction conditions: 20 ( 1 eq.), 21 (3 eq.), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ ( $5 \mathrm{~mol} \%$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$
(3 eq.), $\mathrm{AgOAc}(30 \mathrm{~mol} \%)$; *Yield based on the recovered starting material

The reactions with acrylonitrile and methylvinyl ketone were not found to be encouraged under these conditions. The reaction was sluggish with $N$-isopropyl acrylamide ( $74 \%$ yield based on $48 \%$ conversion). However, the reaction exclusively gave the branched product (22ak). A 1:1 regioisomeric mixture was obtained with styrene. ${ }^{54}$ On the other hand, with dodec-1-ene, the reaction was incomplete ( $65 \%$ yield based on $42 \%$ conversion), ${ }^{55}$ but interestingly, the reaction gave exclusively the linear alkylation product (22am).

## Mechanistic Study

Having encountered and then established the unprecedented branched selective alkylation with acrylates, our next concern was to understand the mechanism of this reaction. The two important issues to be addressed in this context are -i. the mechanism of deprotonation; ii. The possibility of a $\mathrm{Ru}-\mathrm{H}$ intermediate and subsequent hydrometallation (Murai's type mechanism). ${ }^{23}$ There have been four possible mechanisms proposed for the C-H deprotonation - i. oxidative addition; ii. sigma-bond metathesis; iii. electrophilic substitution and iv. 1,2-addition. ${ }^{56}$ Coming to the $\mathrm{Ru}($ II $)$-complexes, in many of the instances it has been proposed thatthe reaction proceeds via the electrophilic substitution. The generally proposed mechanism proceeding via electrophilic substitution involves an intramolecular deprotonation assisted by a carbonate or carboxylate. However, in case of ruthenium-arene complexes, especially when pyridine was a directing group, Dixneuf and co-workers have revealed that
this is intermolecular in nature and is an autocatalytic process - i.e the released carboxylic acid will enhance the rate of deprotonation (Fig. 3.3). ${ }^{57}$

Figure 3.3: Dixneuf's approach for possibility of deprotonation by acetate ${ }^{57}$

Considering these issues, the deuterium labelling experiments have been carried out in order to understand the course of the deportation and also the possibility of the hydrometalation.

Scheme 3.5. Deuterium labeling experiments

Table 3.5.Deuterium labeling experiments with 20c

| S.No | Additive |  | \% of deuterium labelling |  |
| :---: | :--- | :---: | :---: | :---: |
|  |  | $\mathrm{C} 3(\%)$ | $\mathrm{C}^{\prime}{ }^{\prime}+\mathrm{C}^{\prime}(\%)$ |  |
| 1 | AgOAc (30 mol\%) | 100 | 95 |  |
| 2 | $\mathrm{~K}_{2} \mathrm{CO}_{3}$ (3 eq.) | 53 | 46 |  |
| 3 | no additive and base | 87 | 75.5 |  |
| 4 | AgOAc (30 mol\%) <br> $\mathrm{K}_{2} \mathrm{CO}_{3}$ (3 eq.) | 58 | 15.5 |  |

The reactions were conducted in the presence of $\mathrm{D}_{2} \mathrm{O}$ and without acrylate. As shown in Scheme 3.5, the deuterium incorporation was observed at the C3 position of benzofuran and also at the $\mathrm{C}^{\prime} /{ }^{\prime} \mathrm{C}^{\prime}$ ' position of the pendant aryl ring. The magnitude of the deuterium incorporation seems to depend upon the presence and/or absence of the additives (Table 3.5). With the $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ alone, the deuterium incorporation was found to be better than when all the other additives were present. The maximum deuterium incorporation ( $100 \%$ at C 3 and $95 \%$ at C2'/C6') was observed when silver acetate was used as anditive along with the ruthenium complex. This observation reveals that the path of the reaction presumably involves an acetate assisted deprotonation of the $\mathrm{C}-\mathrm{H}$ bond, as proposed by Dixneuf and others in the [Ru]-catalyzed directed arylations. Surprisingly, the reactions, either with potassium carbonate (3 eq. with respect to the benzofuran) alone or along with AgOAc , resulted in a dramatic decrease in the deuterium labelling at both the carbons.

Having been prepared the C3 deutirated benzofuran 20c, next we examined its alkylation with acrylate under the optimized conditions. As shown in Scheme 3.5, quite interestingly, the incorporation of deuterium at the $\beta$-position of the branched product was observed. However, the percentage of deuterium incorporation was quite nominal ( $<10 \%$ ). Similarly, the loss of deuterium at C2'and C6' of the benzoyol group was also noticed. These experiments revealed that the $\mathrm{C}-\mathrm{H}$ activation process is reversible and also that maybe there was no hydride mechanism involved. Very recently, Rouquet and Chatani have revealed a similar observation in the [Ru]-catalyzed o-alkylation of aromatic amides with $\alpha, \beta$ unsaturated ketones and remarked that the involvement of $[\mathrm{Ru}]-\mathrm{H}$ species in the catalytic cycle is yet to be clarified (Scheme 3.6). ${ }^{45}$

Scheme 3.6: Chatani'sapproach for deuterium labelling study ${ }^{45}$
After having obtained some clues from the deuterium labelling experiments next we proceeded further in the direction of understanding the course of the branched selective alkylation. Some of the observations need to be highlighted (Fig.3.4). As shown in Figure

#### Abstract

3.4 , the outcome of the $\mathrm{C}-\mathrm{H}$ functionalization completely depends upon the electronic nature of the olefin employed. In general, with the electron deficient olefins, the branched selectivity is greater. Whereas with partially polarized styrene, a 1:1 mixture of both linear and branched products was obtained and with dodec-1-ene, the complete linear product was obtained. On the other hand, when acetyl was a directing group (with more nucleophilic carbonyl), the selectivity dropped to $1: 1$. Also, when dioxane was employed as a solvent in lieu of toluene that has been generally used, the selectivity dropped to $4: 1$. Another important point to be mentioned here is, during our initial exploratory experiments, under similar conditions, the linear selective alkylation was noticed with the Ru-arene complex.

This catalyst dependent regioselectivity under the similar conditions suggests that the active catalysts involved in these two processes are different in both their steric and their electronic preferences. With the complex $\mathrm{B}\left(\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}\right)$, the observed branched selectivity with methyl acrylate, the lack of regioselectivity with partially polarized styrene and the complete linear selectivity with dodec-1-ene reveals that the partial charge present on the metal centre, inter alia the low polarity of the $\mathrm{Ru}-\mathrm{C}$ bond in the ruthenocycle intermediate involved does not alone decide the orientation of the olefin for its insertion into the $\mathrm{Ru}-\mathrm{C}$ bond. However, the exclusive formation of linear products with methyl methacrylate indicates steric crowding around the metal centre and therefore suggests the presence of overriding steric effects. The large steric effect of $L_{3}=\left(\mathrm{PPh}_{3}\right)_{3}$ with respect to $\mathrm{L}_{3}=$ arene likely influences the insertion of the alkene into the $\mathrm{Ru}-\mathrm{C}$ bond, taking the functional group far from the $\mathrm{PPh}_{3}$ ligands.

All these observations indicate that in the course of the reaction, $\mathrm{Ru}-\mathrm{C}$ bond of the intermediate ruthena-cycle involved is non-polar in nature and is susceptible for electronic perturbations from either side. When either directing group is strong or the reaction medium is polar, there is a chance for partial polarization of this bond and thus the selectivity drops. Finally, the exclusive formation of linear products with methyl methacrylate indicates steric crowding around the metal center and therefore suggests the presence of overriding steric effects.

The discrimination in the olefin orientation seems to be originating from the electronic influence as the sterically demanding methacrylate exclusively gave the linear product. Such a type of electronic discrimination and regioselectivity switching either by polarity of the substrate or because of the electronic nature of the ligands around the metal
centre has been revealed earlier in the hydrometalation step by the groups of Spencer and Yu. ${ }^{58,59}$

Figure 3.4: Hydroarylation (Yu's proposal) on the hydrometalation and similar proposal
Analogous to the hypothesis that has been extended by Yu and co-workers in case of hydroarylation and with the information available in hand, herein, we propose that, there exist two possible pathways for the coordinative insertion. In path $A$, the $\beta$-carbon of the acrylate is oriented close to the metal centre whereas in path $B$, the $\alpha$-carbon is close to the metal centre. While the former leads to the branched product the latter should provide the linear product. The preference for paths A and B will be determined by the partial charge present on the metal centre. In case the metal-carbon bond is non polar, the path A is preferred on the steric grounds, which we believe is indeed operational in the present case. The increase in the branched selectivity in case of 20cwhere a methoxy group is present at para-to the carbonyl group and can retard the metal back donation to the $\pi$-system of the carbonyl group, the lack of regioselectivity with partially polarized styrene and the complete linear selectivity with 1 dodecene supports our arguments.

On this basis, and considering previous reports, a plausible pathway is proposed (Scheme 3.7).The reaction of complex $\mathbf{B}$ with 2 eq. of AgOAc generates $\mathrm{Ru}(\mathrm{OAc})_{2}\left(\mathrm{PPh}_{3}\right)_{3}$. The coordination of the carbonyl group and the subsequent acetate-mediated deprotonation leads to the intermediate ruthenacycleI and releases AcOH . The easy dissociation of the $\mathrm{AcO}-$ $\mathrm{Ru}(\mathrm{II})$ bond from complex Ifavours thecationic intermediate II. Here, there exist two possible pathways for the olefin coordination and its insertion. In path A , observed for $\mathrm{L}_{3}=\left(\mathrm{PPh}_{3}\right)_{3}$, the $\beta$-carbon of the acrylate is oriented close to the metal center due to steric interactions of the functional group (IIIa). On the other hand in path B for $\mathrm{L}_{3}=$ arene, the $\mathrm{Ru}-\mathrm{C}$ bond, is more polar (IIIb) and the $\alpha$-carbon is close to the metal center. While the former pathway leads to the branched product precursor IVa the latter pathway should provide the linear product precursor $\mathbf{I V b}$. Subsequent insertion of the acrylate and a final protodemetalation by AcOH affords 22a/23a and thus regenerates the ruthenium acetate complex.

Scheme 3.7: Proposed mechanism for the hydroarylation

An alternative mechanism involving a $[\mathrm{Ru}]-\mathrm{H}$ (like in the Murai reaction) intermediate and subsequent hydrometalation and final reductive elimination is also possible for $\mathrm{Ru}_{3}(\mathrm{CO})_{12}$ and $\mathrm{RuH}_{2}(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{3}$ leading to regioselectivity similar to catalyst $\mathbf{B}$ $\left(\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}\right)$. However, under the conditions employed in the present case, the possibility of a $\mathrm{Ru}[0]$ species generation for insertion into the $\mathrm{C}-\mathrm{H}$ bond is doubtful.

## $\mathbf{C}-\mathbf{H}$ functionalization pyridine as directing group

After the initial success documented by Miura on the Ru-catalyzed carboxylate directed oxidative cross coupling, reactions with acrylates via C-H activation (cross dehydrogenative coupling) has seen a wide range of applications in this area. Apart from the carbonyl group, various other functional groups have been depoloyed as the directing ligands in this context. Amongst them, pyridine is one of the important directing groups that have been employed recently by Takai and co-workers in the area of Re-catalyzed cross dehydrogenative couplings. As has been indicated in the introduction, with simple 2arylpyridine derivatives, the reaction with acrylates in general proceeds in a linear fashion resulting in the cross-dehydrogenative coupling products. However, such pyridine directed couplings on benzofuran or on any other heterocyclic systems have not yet been documented.

Figure 3.5:Directing group influence on mode of $C-H$ functionalization
After having established benzoyl as a directing group for alkylation, and having studied the factors that influence the branched selectivity as well as, the directing group influence on the mode of $\mathrm{C}-\mathrm{H}$ functionalization, our next concern was what happens if the directing group is strongly ligating like pyridine. As given in the above Figure 3.5, one can see that the competition between linear and branched alkylation depends upon both the electronic preferences of the directing group and also of olefin. Under the same conditions, conjugated olefin gave mainly branched alkylation whereas the simple dodec-1-ene gave exclusively linear alkylation. On the other hand, with same methyl acrylate, when the directing group was acetyl, the proportion of the linear alkylation (when compared with benzoyl directing group) was increased. Also, the branched selective alkylation with acrylate was higher in toluene and decreased when dioxane was employed as the solvent. As mentioned in the previous mechanistic discussion, we reasoned that this was because of the low polarity of the $\mathrm{Ru}-\mathrm{C}$ bond in the involved ruthenacycle intermediate was susceptible for simple electronic effects induced by the substituents present on either the aroyl or the benzofuran rings. Funded upon these observations and to provide further support to the hypothesis on the involvement of the lowpolarity of the $\mathrm{Ru}-\mathrm{C}$ bond, we have been further interested to look at the C3 alkylation of benzofuran employing pyridine as a directing group. As shown in Figure 3.5, we reasoned that due to the strong donation from the pyridine ring the $\mathrm{Ru}-\mathrm{C}$ in the intermediate ruthena cycle will be more polarized and thus favour the
coordination of the olefin based upon the electronic preferences i.e - the electrophilic $\beta$ carbon of the acrylate should be close to the nucleophilic $\mathrm{Ru}-\mathrm{C}$ bond and thus should provide the linear alkylation product.

Figure 3.6: The starting compounds for the alkylation.
Our ventures in this direction started with the preparation of the $2\left(2^{\prime}-\right.$ pyridyl)benzofurans27a-27c by the Sonogashira coupling of 2-ethynylpyridine with the corresponding 2 -iodophenols. Our initial studies were carried out by employing 27a as a substrate and methyl acrylate as the coupling partner. Under the same conditions that have been employed with the 2-benzoylbenzofuran, the reaction of $\mathbf{2 7 a}$ with methyl acrylate gave exclusively one product the structure of which has been established as given in Table3.6 with the help of spectral data analysis. For example in the ${ }^{1} \mathrm{H}$ NMR spectrum of the compound 29aa, olefinic protons were seen to resonate at $\delta 6.74$ and 9.02 ppm as two doublets respectively with the coupling constant of 16.5 Hzindicating the presence of a double bond withE-configuration. The methoxy protons resonated at $\delta 3.86 \mathrm{ppm}$ as a singlet, and most importantly, the disappearance of C3-H was observed. In the HRMS, the exact mass of the compound showed as calculated for $\mathrm{C}_{17} \mathrm{H}_{14} \mathrm{O}_{3} \mathrm{~N}\left(\mathrm{M}^{+}+\mathrm{H}\right)$ was 280.0968 and it was found as280.0968.

Although the linear selectivity is anticipated on the basis of the above mentioned hypothesis of strong coordinative ability of the pyridine unit, however, the observed complete cross-dehydrogenative coupling without any alkylation product was surprising, since no cooxidant was employed. However, considering the fact that the base was employed in excess and that in Heck-like couplings it is known that the base plays the essential role of facilitating the final reductive $\beta$-elimination step, control experiments were carried out in the absence of base. Interestingly, when the reaction was conducted under identical conditions except the absence of base, the reaction provided exclusively the linear alkylation product with complete
regioselectivity. This is an important observation which revealed that with this Ru-complex, the alkylation reactionsare proceeding through the commonly proposed coordinative insertion mechanism and that there is no involvement of any $\mathrm{Ru}-\mathrm{H}$ intermediate.

Table 3.6.Catalyst screening for directed hydroarylation ${ }^{\text {a,b }}$

| S.No | catalyst | $\mathrm{K}_{2} \mathrm{CO}_{3}$ | 28aa (yield \%) | 29aa (yield \%) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ | presence | no | 59 |
| 2 | $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ | absence | 75 | no |
| 3 | $\mathrm{Ru}_{3}(\mathrm{CO})_{12}$ | absence | no | 68 |
| 4 | $\left[\mathrm{Ru}(\mathrm{p}-\text { cymene }) \mathrm{Cl}_{2}\right]_{2}$ | absence | 66 | no |

${ }^{\mathrm{a}}$ Reaction conditions: benzofuran ( 1 eq .), acrylate (3 eq.), catalyst ( $5 \mathrm{~mol} \%$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$ (3eq. and otherwise it mentioned ), $\operatorname{AgOAc}(30 \mathrm{~mol} \%), 140{ }^{\circ} \mathrm{C}$, toluene, 24 h . ${ }^{\text {b }}$ isolated yield after column chromatographic purification.

The structure of the linear alkylation product 28aa has been confirmed by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and HRMS. In ${ }^{1} \mathrm{H}$ NMR spectrum of compound 28aa, the two $\mathrm{CH}_{2}$ protons were seen to resonate at $\delta 2.83$ and $\delta 3.58 \mathrm{ppm}$ as two triplets with a coupling constant $J=8.1$ Hzand most importantly, the disappearance of the C3-H was observed. In the HRMS, the exact mass of the compound showed as calculated for $\mathrm{C}_{17} \mathrm{H}_{16} \mathrm{O}_{3} \mathrm{~N}\left(\mathrm{M}^{+}+\mathrm{H}\right)$ was 282.1125 and it was found as282.1125. The results are summarized in Table 3.6.

Having discovered two complementary conditions for alkylation or alkenylation, we explored the generality of these reactionsby employing a wide range of olefins and differently substituted benzofuran derivatives. Table 3.7 summraizes the results obtainedwith the alkylation reaction (absence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ ). Various acrylates such as ethyl-, butyl-, tert.butyland 4-tert.butylcyclohexyl- acrylates (21b, 21c, 21n and 21orespectively) were compatible and gave the corresponding products in moderate to good isolated yields. However, the reactions with $N$-isopropylacrylamide as well as with methyl crotonate, were found to be sluggish and the products were obtained in poor yields. Quite interestingly, with acrylonitrile $\mathbf{( 2 1 j})$, the reaction proceeded smoothly and both the alkylated product 28aj and the alkenylated product 29aj were obtained in a 1:1 ratio as indicated in Table 3.7. The presence of the electron withdrawing substituent on the benzofuran ring has, at most, only nominal
influence on the selectivity. Interestingly, when a methyl group is present in place of chlorine, the yields were found to drop slightly. These observations indicate that the $\mathrm{C}-\mathrm{H}$ bond strength of the C 3 carbon of benzofuran and the steric environment of the substrate has some influence on the yield of the reaction.

Table 3.7:Acrylate and substrate scope for alkylation ${ }^{\text {a,b }}$

${ }^{\mathrm{a}}$ Reaction conditions: benzofuran (1 eq.), acrylate (3 eq.), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(5 \mathrm{~mol} \%), \mathrm{AgOAc}(30 \mathrm{~mol} \%), 140{ }^{\circ} \mathrm{C}$, toluene, 24 h . ${ }^{\mathrm{b}}$ isolated yield after column chromatographic purification.

Table 3.8 shows the generality of the alkenylation(presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ ) of various 2pyridiylbenzofurans.Various olefin counterparts such as ethyl-, butyl-, tert.butyl- and 4-tert.butylcyclohexyl- acrylates (21b, 21c, 21n and21o respectively) were compatible and gave the corresponding linear selective alkenylated products in moderate to good isolated yields. In this case toothe reaction with $N$-isopropylacrylamide was seen to be sluggish. Surprisingly, with acrylonitrile ( $\mathbf{2 1 j} \mathbf{j}$, even in the presence of the base, both the alkylated product 28aj and the alkenylated product 29aj were obtained in a 1:1 ratio (Table 3.8).

Table 3.8: Acrylate and substrate scope for alkenylation ${ }^{\text {a,b }}$

${ }^{\mathbf{a}}$ Reaction conditions: benzofuran (1 eq.), acrylate (3 eq.), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(5 \mathrm{~mol} \%$ ), K 2 CO 3 (3 eq.), $\mathrm{AgOAc}(30 \mathrm{~mol} \%), 140^{\circ} \mathrm{C}$, toluene, 24 h . ${ }^{\mathrm{b}}$ isolated yield after column chromatographic purification.

Funded upon our initial hypothesis we extended the following mechanism for these two reactions. The reaction of $\mathrm{RuCl}_{2}\left(\mathrm{PPh}_{3}\right)_{3}$ complex with 2 eq. of AgOAc generates $\mathrm{Ru}(\mathrm{OAc})_{2}\left(\mathrm{PPh}_{3}\right)_{3}$. The coordination of the pyridyl nitrogen and the subsequent acetatemediated deprotonation leads to the intermediate ruthenacycleI and releases AcOH. The easy dissociation of the $\mathrm{AcO}-\mathrm{Ru}(\mathrm{II})$ bond from complexI favours the coordination of the olefin to the cationic intermediate II. Due to the more polar $\mathrm{Ru}-\mathrm{C}$ bond present in complex IIIb, the electrophilic $\beta$-carbon is close to the nucleophilic Ru-C carbon atom. After the olefin insertion and acetate addition, the linear product precursor IV will be obtained. When there was no base present, this intermediate upon protodemetallation by the released AcOH affords the linear alkylation product and thus regenerates the ruthenium acetate complex. When the base is present, since the $\beta$ - elimination (commonly encountered in Heck-coupling) is not possible as it requires that $\mathrm{M}-\mathrm{C}_{\alpha}$ and $\mathrm{C}_{\beta}-\mathrm{H}$ bonds align in a syn coplanar arrangement, we propose that this happens via the base-mediate hydride abstraction through the anchimeric assistance of the metal centre present on the next carbon.

Scheme 3.7: Proposed mechanism for the alkylation and alkenylation

## Conclusions

We have documented a first report on the hydroarylation of alkyl acrylates via $\mathrm{C}-\mathrm{H}$ activation. This is the much awaited Murai Reaction with acrylates employing Ru-catalysts and more importantly, the substrates employed are pharmaceutically relevant. The remarkable features of the present transformations are - i. the unprecedented regioselectivity of the coupling process when the directing group was a benzoyl; ii. the base switch for the alkylation or alkenylation when the pyridine ring was the directing group. Overall we have provided the first examples in this direction - how the regioselectivity of acrylate insertion depended upon the steric and their electronic preferences of the active catalysts involved and how the electronic preferences around the metal centre will vary with the directing group employed. We believe that these findings will provide fresh impetus for further efforts on understanding the "hydroarylation process via C-H activation", especially in the direction of how the nature of the substrate, catalyst, ligand, and base will be fine-tuned in order to achieve the alkylations with the desired regioselectivity.

## General procedure A: Hydroarylation of acrylates employing $\mathbf{R u}\left(\mathbf{P P h}_{3}\right)_{3} \mathbf{C l}_{\mathbf{2}}$ complex

2-aroylbenzo[b]furan ( 0.1 mmol ) was placed in a screw cap pressure tube and dissolved in anhydrous toluene, which was then evacuated and back filled with argon. To the reaction vessel alkene (acrylate) ( 0.3 mmol ), $\mathrm{K}_{2} \mathrm{CO}_{3}(0.3 \mathrm{mmol}), \mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ ( 0.005 mmol ) and $\mathrm{AgOAc}(0.03 \mathrm{mmol})$ were added. The solution was then stirred at $140{ }^{\circ} \mathrm{C}$ (bath temperature) for 12 h . The reaction mixture was cooled to room temperature. The solvent were evaporated and the crude products were purified by column chromatography (pet ether/AcOEt) to give analytically pure.

Methyl 2-(2-benzoylbenzofuran-3-yl)propanoate (22aa): Isolated by column chromatography (pet.ether/AcOEt $=9: 1, \mathrm{R}_{f}=0.5$ ). The title compound was determined as colourless oil ( $87 \%$ ), and the ratio of branch to linear product is (94:6). ${ }^{1} \mathrm{H}$ NMR (200 $\mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 1.67(\mathrm{~d}, J=7.2 \mathrm{~Hz}, 3 \mathrm{H}$ ), $3.68(\mathrm{~s}, 3 \mathrm{H}), 4.96$
 $(\mathrm{q}, J=7.2 \mathrm{~Hz}, 1 \mathrm{H}), 7.32(\mathrm{ddd}, J=1.4,6.8,8.1 \mathrm{~Hz}, 1 \mathrm{H}), 7.45-7.68(\mathrm{~m}, 5 \mathrm{H}), 7.75(\mathrm{~d}, J$ $=8.0 \mathrm{~Hz}, 1 \mathrm{H}), 8.10-8.16(\mathrm{~m}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $50 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 16.8(\mathrm{q}), 35.9(\mathrm{~d})$, 52.2 (q), 112.5 (d), 122.2 (d), 123.7 (d), 126.7 ( s), 128.1 (d), 128.3 (d, 2C), 128.8 (s), 129.9 (d, 2C), 132.9 (d), 137.3 (s), 147.7 (s), 154.3 (s), 173.7 (s), 185.9 (s) ppm; IR(neat): $v 3020,2400,1735,1645,1563,1261,1215,1059,877,757,669 \mathrm{~cm}^{-1}$; HRMS(ESI) calcd for $\mathrm{C}_{19} \mathrm{H}_{16} \mathrm{O}_{4} \mathrm{Na}\left(\mathrm{M}^{+}+\mathrm{Na}\right)$ : 331.0941; found: 331.0938.

Ethyl 2-(2-benzoylbenzofuran-3-yl)propanoate (22ab): Isolated by column chromatography (pet.ether/AcOEt $=9: 1, \mathrm{R}_{f}=0.5$ ). The title compound was determined as colourless oil ( $88 \%$ ) and the ratio of branch to linear product is (92:8). ${ }^{1} \mathrm{H}$ NMR (200 $\mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 1.15(\mathrm{t}, J=7.2 \mathrm{~Hz}, 3 \mathrm{H}), 1.67(\mathrm{~d}, J=7.3 \mathrm{~Hz}$,

General procedure B: Linear alkenylation using $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ :

2-(benzofuran-2-yl)pyridine ( 0.1 mmol ) was placed in a screw cap pressure tube and dissolved in anhydrous toluene ( 2 mL ), which was then evacuated and back filled with argon. To the reaction vessel alkene (acrylate) ( 0.3 mmol ), $\mathrm{K}_{2} \mathrm{CO}_{3}(3.0 \mathrm{mmol})$, $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(0.005 \mathrm{mmol})$ and $\mathrm{AgOAc}(0.03 \mathrm{mmol})$ were added. The solution was then stirred at $140{ }^{\circ} \mathrm{C}$ (bath temperature) for 24 h . The reaction mixture was cooled to room temperature. The solvent were evaporated and the crude products were purified by column chromatography (pet ether/AcOEt) to give analytically pure.

Methyl (E)-3-(2-(pyridin-2-yl)benzofuran-3-yl)acrylate (29aa): Isolated by column chromatography (pet.ether/ $\mathrm{AcOEt}=8: 2, \mathrm{R}_{f}=0.5$ ). The title compound was determined as pale yellow colour solid (77\%). General procedure B: Linear alkylation using $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}$ :
2-(benzofuran-2-yl)pyridine ( 0.1 mmol ) was placed in a screw cap pressure tube and dissolved in anhydrous toluene ( 2 mL ), which was then evacuated and back filled with argon. To the reaction vessel alkene (acrylate) ( 0.3 mmol ), $\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}_{2}(0.005$ $\mathrm{mmol})$ and $\mathrm{AgOAc}(0.03 \mathrm{mmol})$ were added. The solution was then stirred at $140{ }^{\circ} \mathrm{C}$ (bath temperature) for 24 h . The reaction mixture was cooled to room temperature. The solvent were evaporated and the crude products were purified by column chromatography (pet ether/AcOEt) to give analytically pure.

## Methyl 3-(2-(pyridin-2-yl)benzofuran-3-yl)propanoate

## LIST OF PUBLICATIONS:

is "The influence of electronic factors on Pd-mediated cycloisomerization: a systematic investigation of competitive 6 -exo-dig versus 7 -endo-dig cyclizations of sugar alkynols." Yadagiri Kommagalla, I. Boddeti, B. Srinivas, M. N. Deshmukh, R.G. Gonnade and C.V. Ramana, Tetrahedron, 2009, 65, 9819-9832.
is "Target cum flexibility: simple access to benzofuran conjugated sugar and nucleoside derivatives." Yadagiri Kommagalla, Kolluru Srinivas and C.V. Ramana, Tetrahedron Lett, 2013, 64, 1824-1827.
is " $[\mathrm{Ru}]$-Catalysed Complementary Branched and Linear C(3)-Alkylation of 2Aroylbenzofurans with Acrylates" Yadagiri Kommagalla, Kolluru Srinivas and C.V. Ramana, (manuscript under revision).
is "Optimization of the phosphoinositol-3, 4, 5-triphosphate antagonist PITENIN-1." Yadagiri Kommagalla, Cornea, S., Riehle, R., Torchilin, V., Degterev, A., C.V. Ramana, (Communicated).
is "Synthesis, characterization, antifungal evaluation and mechanistic studies of new 1, 2, 3 triazole derivatives." Yadagiri Kommagalla, Santosh G. Tupe, M. V. Deshpande and C.V. Ramana (to be Communicated).
is " [Ru]-Catalysed Switchable C-H activation: alkenylation and alkylation of benzofuranyl
pyridine." Yadagiri Kommagalla and C.V. Ramana (to be communicated).

## List of Patents:

is Small Molecule Inhibitors of PI3-Kinase Signaling. Degterev, A., C.V. Ramana, Torchilin, V., Yadagiri Kommagalla, Cornea, S., (US provisional patent accepted, No: 61/802,960).
it A Novel Process for the Preparation of Anti-Inflammatory Compounds. C.V. Ramana, Yadagiri Kommagalla, K. Srinivas, (WO, IN provisional patent accepted, No:1876DEL2013).
is New 1,2,3 triazole derivatives as anti-fungal drugs. C.V. Ramana, M.V. Deshpande, Yadagiri Kommagalla, Santosh G. Tupe, (WO, IN provisional patent has filed).

Erratum
