## Studies Towards Synthesis of $\boldsymbol{\beta}$-Herbertenol And Other

## Biologically Active Molecules

A Thesis

Submitted to the

UNIVERSITY OF PUNE
for the degree of

## DOCTOR OF PHILOSOPHY

in

## CHEMISTRY

by

## MAHESH THAKKAR

Division of Organic Chemistry (Technology)
National Chemical Laboratory
Pune-411 008, India

November 2006

## CERTIFICATE

Certified that the work incorporated in the thesis entitled "Studies Towards Synthesis of $\boldsymbol{\beta}$ Herbertenol And Other Biologically Active Molecules" submitted by Mahesh Thakkar was carried out under my supervision. Such material as has been obtained from other sources has been duly acknowledged in the thesis.

November, 2006
Subhash P. Chavan
National Chemical Laboratory Research Supervisor

## DECLARATION

I hereby declare that the thesis entitled "Studies Towards Synthesis of $\boldsymbol{\beta}$-Herbertenol And Other Biologically Active Molecules" submitted for Ph. D. degree to the University of Pune has been carried out at Organic Chemistry: Technology Division, National Chemical Laboratory, Pune, under the supervision of Dr. Subhash P. Chavan and the work is original and has not been submitted in part or full by me for any degree or diploma to this or any other university.

## Acknowledgement

It gives me great pleasure to express my deep gratitude to my research guide, Dr. Subhash P. Chavan, for his inspiring guidance and never diminishing encouragement through out my research program.

I am thankful to Dr. S. K. Kamat and Dr. U. R. Kalkote for their affection, suggestions and helping me to speed up work through out my research program.

I am also thankful to Dr. M. K. Gurjar (Head, Organic Chemistry: Technology Division) and Dr. Sivaram (Director, NCL) for permitting me to work in NCL. Help rendered from all the senior scientists Mrs. Latha Sivadasan, Dr. C. V. Ramana, Dr. D. K. Mohapatra, Dr. R. A. Joshi, Mrs. R. A. Joshi, Dr. H. B. Borate, Mr. I. Shivakumar, Dr. Muthukrishnan, Dr. (Mrs.) R. D. Wakharkar, Dr. (Mrs.) Bhanu Chanda, Dr. A. Murugan and Dr. Ramalingam of NCL is gratefully acknowledged.

I am equally thankful to Dr. K. B. Nayar and Dr. Jigar Desai, under whom I have done my M. Sc. dissertation. I am also grateful to Dr. Milind Gharpure for encouraging me and directing me to NCL for research.

I am obliged to Takasago International Corporation, Japan for generous gift of ( $R$ )-(+)-citronellal.

My sincere thanks for the help rendered by my labmates Shivashankar, Rajendra Kharul, Ramesh, Pasupathy, Ramakrishna, Praveen, Sambhaji, Dushyant, Pallavi, Sanjay, Swapna, Sudheer, Vikas, Ashok, Dhawane, Jogdand, Sharad, Abhijeet, Kishor, Lalit, Aadinath, Mayur, Sandeep Shinde, Smita, Suman, Pawar, Nilesh, Pandeyji who helped me through various phases of my tenure in the lab. I would like to thank all my friends in and out of NCL; Amit Patwa, Sandeep Jain, Arvind Jangid, Pooja Akolkar, Sunita Sing, Amar Ballabh, Kamlesh, Sunil, Shivanand Pai, Uddhavesh, Kishor, Nagendra Sharma, Bhalchandra, Sachin, Kannan, Sushil, Baag, Sanjeeb, Mukulesh, Eswar, Subbu, Vijayraaj, Khirud, Victor, Ram, Arun, Satyendra Pandey, Ravi, Ganesh, Aarif, Nilesh, Kesari, Nagendra Kondekar, Puspesh, Pradeep, Rehmaan, Shankar, Swaroop, Rajendra, Sanjay, Sud, Nitin, Zakir, Bhushan, Ekambaram, Kiran, Mahesh, Siddarth, Dhanonjay, Vishal, Mallikarjuna, Mandaar, Raman, who helped me in my research work and made my tenure at NCL cheerful.

Words fall short to thank my parents, who have contributed and sacrificed a lot for me to reach this stage and will always remain a sole source of inspiration in my life. The thesis is a form to pay respect to their attributes.

I would also like to thank Poorva and Pallavi, for their constant encouragement and helpful suggestions.

I wish to thank office staff (Mr. Balan, Mrs. Kulkarni, Mrs. Catherine, Mr. Fernandis, Mr.Tikhe, Mr. Vardharajan, Mr. Ranawade, Mr. Kakade, Mr. Bhise, Mr. Sambhu, Mr. Bhosale) for the help whenever required. I would also like to acknowledge all the staff members of NMR, Microanalysis, Special Instruments Lab and Library for their assistance during the course of my work.

Finally I thank CSIR, New Delhi, for financial support.

NCL, Pune
Mahesh Thakkar

1. All melting points and boiling points are uncorrected and the temperatures are in the centigrade scale.
2. The compound numbers, scheme numbers and reference numbers given in each section refers to that particular section only.
3. All solvents were distilled before use. Petroleum ether refers to the fraction boiling in the range of $60-80^{\circ} \mathrm{C}$.
4. Organic layers were dried over anhydrous sodium sulfate.
5. The reaction progress was monitored by the TLC analysis using thin layer plates pre-coated with silica gel 60 F254 (Merck) and visualized by fluorescence quenching or iodine or by charring after treatment with $p$-anisaldehyde.
6. In cases where chromatographic purification was done, silica gel (60-120 or 230400 mesh) was used as the stationary phase or otherwise as stated.
7. IR spectra were recorded on a Perkin-Elmer Infrared Spectrophotometer Model 68B or on a Perkin-Elmer 1615 FT Infrared spectrophotometer.
8. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on Bruker AV-200 (50 MHz) or Bruker AV-400 (100 MHz) or Bruker DRX-500 (125 MHz). Figures in the parentheses refer to ${ }^{13} \mathrm{C}$ frequencies. Tetramethylsilane was used as the internal standard.
9. Optical rotations were recorded at ambient temperature on JASCO Dip-181 digital polarimeter using sodium vapor lamp.
10. Mass spectra were recorded at ionization energy 70 eV on Finnigan MAT-1020, automated GC/MS instrument and on API Q STARPULSAR using electron spray ionization [(ESI), solvent medium: a mixture of water, acetonitrile and ammonium acetate] technique and mass values are expressed as $\mathrm{m} / \mathrm{z}$. HRMS were recorded on a micromass Q-T of micro with spray source (ESI ${ }^{+}$) mode.
11. Starting materials were obtained from commercial sources or prepared using known procedures.
12. Microanalytical data were obtained using a Carlo-Erba CHNS-O EA 1108 Elemental analyzer, within the limits of accuracy ( $\pm 0.4 \%$ ).

#### Abstract

The thesis entitled "Studies Towards Synthesis of $\boldsymbol{\beta}$-Herbertenol And Other Biologically Active Molecules" is divided into three chapters.

Chapter-1 : deals with the enantiospecific synthesis of $\beta$-herbertenol, and is further divided into two sections.

Chapter-2 : reports enantiospecific syntheses of (-)-parvifoline, (+)-isoparvifolinone and (-)-curcuquinone; and is divided into three sections.

Chapter-3 : describes an enantiospecific synthesis of heritol.

\section*{Chapter-1 : Enantiospecific Synthesis of $\boldsymbol{\beta}$-Herbertenol}

\section*{Section-1 : Herbertenol : A Brief Review} 

Herbertane skeleton, 1  $(-)-2$

Section-1 begins with a brief introduction to the natural product, (-)- $\beta$-herbertenol 2 and other herbertene type sesquiterpenes. An account of the various synthetic routes of a few of the phenolic herbertanes, which possess 3-methyl-1-(1,2,2-trimethylcyclopentyl) cyclohexane skeleton, is presented briefly.

## Section-2 : Enantiospecific Synthesis of (+)- $\beta$-Herbertenol

Difficulties associated with the construction of the vicinal quaternary carbons in the cyclopentane ring makes herbertanes and cuparanes challenging synthetic targets. Although, there have been synthetic strategies reported towards rac- $\beta$-herbertenol, not a single asymmetric synthesis has been attempted so far. Our interest in these skeletons has led to the synthesis of cuparenone and $( \pm)-\beta$-herbertenol. In continuation of our efforts towards the synthesis of herbertanes and cuparanes, enantiospecific synthesis of (+)- $\beta$ herbertenol was undertaken, where $(R)-(+)$-citronellal has been utilized as a source of
chirality and Taber's protocol of stereospecific C-H insertion by diazodecomposition of $\alpha$ -diazo- $\beta$-ketoester for the construction of cyclopentanones has been employed as the key step, which is presented in this section.

## Scheme-1

Reagents and conditions : a) (i) LDA, THF, $-78^{\circ} \mathrm{C}, 1.5 \mathrm{~h}, \mathrm{TMSCl},-78^{\circ} \mathrm{C}$ to $\mathrm{rt}, 5 \mathrm{~h}$; (ii) NBS, THF, $0^{\circ} \mathrm{C}$, 0.5 h ; (iii) $\mathrm{Li}_{2} \mathrm{CO}_{3}, \mathrm{LiBr}, \mathrm{DMF}, 130-140^{\circ} \mathrm{C}, 4 \mathrm{~h}, 75 \%$ from 3; b) (i) $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{Me}_{2} \mathrm{SO}_{4}$, acetone, reflux, $12 \mathrm{~h}, 90 \%$; (ii) $\mathrm{OsO}_{4}$ (cat), Jones' reagent, acetone, rt, $5 \mathrm{~h}, 80 \%$; c) (i) $\mathrm{SOCl}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, reflux, 2 h ; (ii) Meldrum's acid, pyridine, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 2 \mathrm{~h}$; (iii) MeOH, reflux, $4 \mathrm{~h}, 78 \%$; (iv) $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{MsN} \mathrm{N}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-5{ }^{\circ} \mathrm{C}$ to rt, overnight; d) $\mathrm{Rh}_{2}(\mathrm{OAc})_{4}$ (cat), $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, $35 \%$ for 2 steps; e) $\mathrm{K}_{2} \mathrm{CO}_{3}$, MeI, acetone, rt, $24 \mathrm{~h}, 85 \%$; f) (i) LAH, THF, $0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 5 \mathrm{~h}, 80 \%$; (ii) pivaloyl chloride, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-10^{\circ} \mathrm{C}$ to rt, $4 \mathrm{~h}, 65 \%$; g) (i) $\mathrm{NaH}, \mathrm{CS}_{2}, \mathrm{THF}, 0^{\circ} \mathrm{C}, 2 \mathrm{~h}$, then MeI, rt, $5 \mathrm{~h}, 95 \%$; (ii) TBTH, AIBN (cat), toluene, reflux, $3 \mathrm{~h}, 80 \%$; (iii) LAH, THF, rt, 2 h , quantitative; $h$ ) (i) PDC, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}, 3 \mathrm{~h}$; (ii) $\mathrm{N}_{2} \mathrm{H}_{4}-\mathrm{H}_{2} \mathrm{O}$, diethyleneglycol, $150^{\circ} \mathrm{C}, 4 \mathrm{~h}, 190^{\circ} \mathrm{C}, 3 \mathrm{~h}, 73 \%$ for 2 steps; (iii) $\mathrm{BBr}_{3}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}$ to rt, overnight, $93 \%$.

Accordingly, $(R)-(+)$-citronellal was converted to the enone 3 using literature procedure, which on $\alpha$-halogenation using Hassner's protocol, followed by dehydrohalogenation using lithium bromide and lithium carbonate in hot DMF provided the required phenol 4 in $75 \%$ overall yield (from 3). This phenol 4 was transformed to the key $\alpha$-diazo- $\beta$-ketoester intermediate $\mathbf{6}$ via an acid derivative 5. The crucial C-H insertion reaction was then performed over 6 by using Taber's protocol of diazodecomposition, according to which 6 was treated with catalytic amount $\mathrm{Rh}_{2}(\mathrm{OAc})_{4}$ to furnish cyclic $\beta$ ketoester $\mathbf{7}$ as a mixture of diastereomers. Having secured the key cyclopentanone in place, the remaining problem was to convert 7 to the geminal dialkylated cyclopentane skeleton. Accordingly, ester 7 was methylated using $\mathrm{K}_{2} \mathrm{CO}_{3}$, MeI in dry acetone, which gave a single diastereomer 8 in which methyl group and the aryl group on the adjacent quaternary carbons were anti to each other. The remaining carbonyl group deoxygenation was achieved using common functional group transformations, followed by methyl ether deprotection using $\mathrm{BBr}_{3}$ to provide the required (+)- $\beta$-herbertenol 2 in good yields (Scheme-1).

Thus, (+)- $\beta$-herbertenol has successfully been synthesized enantiospecifically, using naturally occurring $(R)-(+)$-citronellal as the source of chirality. The same idea can be applicable to the synthesis of naturally occurring (-)- $\beta$-herbertenol and other biologically active herbertanes also.

## Chapter-2 : Syntheses of (-)-Parvifoline, (+)-Isoparvifolinone and (-)-Curcuquinone

## Section-1 : Synthesis of Parvifoline \& Curcuquinone : A Brief Review

$11 \mathrm{R}=\mathrm{H}$
$12 \mathrm{R}=\mathrm{Me}_{2} \mathrm{CHCH}_{2} \mathrm{C}(\mathrm{O})$

13

14

The title compound (-)-parvifoline 11, along with isoparvifolinone $\mathbf{1 3}$ and parvifoline isovalerate $\mathbf{1 2}$ are sesquiterpenes, isolated from the genera Coreopsis and

Perezia, and are the only examples of naturally occurring compounds with a trimethylbenzocyclooctane structural unit. The absolute configuration of (-)-parvifoline 11 was established by it's chemical transformation to (-)-curcuquinone 14, a natural product of the known absolute configuration. Section-1 presents a brief introduction of the title sesquiterpenes, and various synthetic routes proposed for their synthesis.

## Section-2 : Enantiospecific Synthesis of (-)-Parvifoline \& (+)-Isoparvifolinone : Friedel-Craft's Acylation Approach For Benzocyclooctane Ring Formation

The construction of an eight membered ring with a deconjugated double bond is the main structural feature that challenges the synthesis of (-)-parvifoline 11. Moreover, introduction of the chirality at the nonfunctionalised benzylic position is difficult as well. Encouraged by the results achieved in the enantiospecific synthesis of ( + )- $\beta$-herbertenol (chapter-1), an enantiospecific synthesis of (-)-parvifoline 11 and (+)-isoparvifolinone 13, using Friedel-Craft's acylation as the key step was designed, which has been described in this section.

Accordingly, $(R)-(+)$-citronellal ( $98 \%$ ee) was converted to the enone 15 (1: 1 diastereomeric mixture) as reported in the literature, which was then converted to the $\alpha$ hydroxyenone 16 using Rubottom's protocol in $70 \%$ overall yield from 15. Methyl group introduction by 1,2 -addition of the Grignard reagent MeMgI over hydroxyenone 16, provided diol 17 as a mixture of diastereomers in $95 \%$ yield. The secondary hydroxyl group oxidation of the diol $\mathbf{1 7}$ under Swern oxidation conditions followed by mesylation of the crude product, resulted in tertiary hydroxyl group elimination with concomitant aromatization, which ended up in the mixture of phenol $\mathbf{1 8}$ and it's mesyl ester. The crude product was further hydrolyzed using KOH in refluxing methanol to give phenol $\mathbf{1 8}$ in $47 \%$ overall yield from diol 17. Methyl ether protection of the phenol 18, followed by dihydroxylation of the olefin functionality and periodate cleavage of the resulting diol gave corresponding aldehyde, over which two carbon olefination using Ando's protocol furnished the required $Z-\alpha, \beta$-unsaturated ester 19 as the sole product in high yields. Ester 19 was then hydrolyzed to the corresponding acid under alkaline hydrolysis conditions, which was further converted to the corresponding acid chloride and immediately subjected to Friedel-Craft's acylation conditions, i. e. treatment with anhydrous aluminium chloride, to furnish cyclic enone 20 in $40 \%$ overall yield from 19 (Scheme-2).

## Scheme-2

Reagents and conditions : a) (i) LDA, THF, $-78^{\circ} \mathrm{C}, 1.5 \mathrm{~h}$, then $\mathrm{TMSCl},-78{ }^{\circ} \mathrm{C}$ to $\mathrm{rt}, 5 \mathrm{~h}$; (ii) $m C P B A, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to rt, 10 h ; (iii) dilute $\mathrm{HCl}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 12 \mathrm{~h}, 70 \%$ overall; b) MeMgI, diethyl ether, $0{ }^{\circ} \mathrm{C}$, then 16, $0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 12 \mathrm{~h}, 95 \%$; c) (i) oxalyl chloride, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-78{ }^{\circ} \mathrm{C}, \mathrm{DMSO}, 15 \mathrm{~min}$, then 17, $30 \mathrm{~min}, E t_{3} \mathrm{~N},-78^{\circ} \mathrm{C}$ to rt, 5 h ; (ii) $\mathrm{MeSO}_{2} \mathrm{Cl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to rt, 3 h , then reflux, 5 h ; (iii) $\mathrm{KOH}, \mathrm{MeOH}$, reflux, 7 h , 47\% overall; d) (i) $\mathrm{Me}_{2} \mathrm{SO}_{4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$, acetone, reflux, 12 h, $86 \%$; (ii) $\mathrm{OsO}_{4}$ (cat), NMO ( $50 \%$ in water), acetone, $\mathrm{rt}, 24 \mathrm{~h}$; (iii) $\mathrm{NaIO}_{4}$ supported over silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, 3 h ; (iv) $\left(\mathrm{o}-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}\right)_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{COOEt}, \mathrm{NaH}, \mathrm{THF},-7{ }^{\circ} \mathrm{C}, 3 \mathrm{~h}, 85 \%$ overall; e) (i) KOH , MeOH , reflux, 3 h ; (ii) oxalyl chloride, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}, 3 \mathrm{~h}$; (iii) $\mathrm{AlCl}_{3}$ (anhydrous), $\mathrm{CH}_{2} \mathrm{Cl}_{2},-20^{\circ} \mathrm{C}$ to rt, $10 \mathrm{~h}, 40 \%$ overall; f) (i) $\mathrm{CeCl}_{3}-7 \mathrm{H}_{2} \mathrm{O}, \mathrm{NaBH}_{4}, \mathrm{MeOH}, 0^{\circ} \mathrm{C}, 30 \mathrm{~min}$; (ii) PCC over silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 2 \mathrm{~h}, 60 \%$ overall; g) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, \mathrm{l} \mathrm{h}, 60 \%$; h) (i) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}(10 \%), \mathrm{MeOH}, 24 \mathrm{~h}$, followed by $\mathrm{NaBH}_{4}, 30$ min, $55 \%$; i) (i) pyridine, p-toluenesulfonylchloride, $-4^{\circ} \mathrm{C}$, 3 days, then 100 ${ }^{\circ} \mathrm{C}, 10 \mathrm{~h}$; (ii) EtSLi, DMF, $105{ }^{\circ} \mathrm{C}, 24 \mathrm{~h}, 58.5 \%$ overall.

The keto functionality of the enone $\mathbf{2 0}$ was then reduced under Luche reduction conditions, followed by 1,3-carbonyl transposition using pyridinium chlorochromate over silica gel to afford isoparvifolinone methyl ether 21 in $60 \%$ overall yield. (+)Isoparvifolinone $\mathbf{1 3}$ was then obtained by $\mathrm{BBr}_{3}$ promoted methyl ether deprotection of $\mathbf{2 1}$ in $60 \%$ yield. Further, intermediate 21 on hydrogenation followed by borohydride reduction and tosylation of the resulting secondary alcohol 22, provided the required parvifoline methyl ether derivative, which on deprotection by lithium thioethoxide in hot DMF gave (-)-parvifoline $\mathbf{1 1}$ in good yields.

Thus, (-)-parvifoline and (+)-isoparvifolinone have been synthesized enantiospecifically, using Friedel-Craft's acylation as the key step.

## Section-3 : Enantiospecific Synthesis of (-)-Curcuquinone \& (-)-Parvifoline : Ring Closing Metathesis Approach

Encouraged by the results achieved in the enantiospecific synthesis of (-)-11, ring closing metathesis reaction was envisaged as the key reaction for benzocyclooctene skeleton formation, in order to decrease the number of steps and to improve the overall yields. The present section describes enantiospecific synthesis of (-)-11 using ring closing metathesis as the key step, and also enantiospecific synthesis of (-)-curcuquinone $\mathbf{1 4}$ utilizing $(R)-(+)$-citronellal as the chiron (Scheme-3 and 4).

Accordingly, the synthesis commenced from diol 17, which was synthesized as described in section- 2 . The secondary hydroxyl group of the diol $\mathbf{1 7}$ was protected as it's acetate 23, followed by 1,3-ketone transposition using pyridinium chlorochromate to furnish the required conjugated ketone 24 . This enone 24 on 1,2-addition with methallyl magnesium chloride under Barbier conditions gave diol 25, which on Dess-Martin periodinane oxidation followed by mesylation of the resulting hydroxy enone 26, provided the required diolefin precursor 27 along with it's mesyl ester. Hydrolysis of the crude product under alkaline conditions provided the requisite intermediate 27 in high yields. Finally, the crucial eight membered ring formation was achieved by ring-closing metathesis of 27 employing second-generation Grubbs' catalyst 28, to furnish (-)parvifoline $\mathbf{1 1}$ in $90 \%$ isolated yield (Scheme-3).

## Scheme-3

Reagents and conditions : a) pyridine, acetyl chloride, $0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 12 \mathrm{~h}, 85 \%$; b) $\mathrm{PCC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 7 \mathrm{~h}, 80 \%$; c) $\mathrm{Mg}, \mathrm{THF}$, methallyl chloride, $0^{\circ} \mathrm{C}, 24 \mathrm{~h}, 90 \%$; d) $\mathrm{DMP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 4 \mathrm{~h}$, $85 \%$; e) (i) $E t_{3} N$, methanesulfonyl chloride, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to rt, 3 h , then reflux, 5 h ; (ii) KOH , MeOH, reflux, $12 \mathrm{~h}, 79 \%$ for two steps; $f$ ) Grubbs' catalyst (second generation) 28, toluene, $80^{\circ} \mathrm{C}$, 5 h, $90 \%$.

## Scheme-4

Reagents and conditions : a) (i) $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{MeOH}, \mathrm{rt}, 30 \mathrm{~min}$; (ii) $\mathrm{DMP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 2 \mathrm{~h}$,; b) (i) $\mathrm{CH}_{2} \mathrm{Cl}_{2}, E t_{3} \mathrm{~N}, \mathrm{rt}, 3 \mathrm{~h}$; (ii) $\mathrm{CAN}, \mathrm{CH}_{2} \mathrm{Cl}_{2}-\mathrm{H}_{2} \mathrm{O}, 0^{\circ} \mathrm{C}, 1 \mathrm{~h}, 60 \%$ overall; c) $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{rt}, 1 \mathrm{~h}$, acetyl chloride, $0^{\circ} \mathrm{C}$ to rt, overnight, $52 \%$ overall.

The synthesis of (-)-curcuquinone $\mathbf{1 4}$ was easily accomplished from enone intermediate 24. It was hydrolyzed using $\mathrm{K}_{2} \mathrm{CO}_{3}$ in methanol followed by Dess-Martin periodinane oxidation and treatment with triethylamine, to give the corresponding hydroquinone derivative, which without purification was subjected to oxidation using CAN as the oxidizing agent to provide (-)-curcuquinone 14 in $60 \%$ overall yield (Scheme-4).

Thus, (-)-parvifoline has been synthesized enantiospecifically, utilizing ( $R$ )-(+)citronellal as the chiron and employing ring closing metathesis as the key step in $10 \%$ overall yield. (-)-Curcuquinone has also been synthesized.

## Chapter-3 : Synthesis of Heritol Using ( $R$ )-(+)-Citronellal

Miles' et al have isolated an active toxin, called heritol 30, a naturally occurring sesquiterpene, from the sap of the mangrove plant Heritiera littoralis, which was shown to possess itchthytoxicity in ppm quantities to Tilapia nilotica fingerlings. It has a novel structure of the cadinane sesquiterpene class with an unusual oxygenation pattern. The relative stereochemistry in heritol $\mathbf{3 0}$ was established by a single crystal X-ray analysis, but it's absolute configuration was just proposed to be $\boldsymbol{R}$ at $\mathbf{C}_{\mathbf{1 0}}$ by it's analogy with other cadinanes. This chapter describes it's reported syntheses, and our approach towards enantiopure heritol $\mathbf{3 0}$ and heritonin 31, utilizing $(R)-(+)$-citronellal as the chiron.

Thus, the synthesis initiated from phenol intermediate 18, which was protected as it's methyl ether 32. It was then subjected to Weinreb's condition to give an acid derivative 33 in $82 \%$ yield, which on treatment with trifluoroacetic anhydride underwent smooth cyclisation to furnish the key tetralone intermediate $\mathbf{3 4}$ in $80 \%$ isolated yield. This tetralone 34 was further converted to heritonin $\mathbf{3 1}$ by using Chavan's protocol, according to which it was subjected to 1,2 -addition using ethyl-2-bromopropionate under Reformatsky reaction conditions, followed by acidic work-up to provide $\beta, \gamma$-unsaturated ester 35, which on dihydroxylation furnished diol 36. This diol on treatment with $p$ TSA under refluxing benzene provided heritonin $\mathbf{3 1}$ and it's C-8 epimer (epi-31) in high yields, which were separated by repeated crystallization, and then deprotected to furnish the optically pure
heritol $\mathbf{3 0}$ and it's C-8 epimer (epi-30), respectively. Specific rotation of this synthetically obtained heritol was compared with that of naturally isolated one, and based on this observation absolute configuration of naturally isolated $(+)$-heritol was proposed to be $(S$, $R$ ) at C-10, C-8.

## Scheme-5

Reagents and conditions : a) $\mathrm{Me}_{2} \mathrm{SO}_{4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$, acetone, reflux, $12 \mathrm{~h}, 86 \%$; b) $\mathrm{OsO}_{4}$ (cat), Jones' reagent, acetone, $r t, 7 h, 82 \%$; c) triflouroacetic anhydride, triflouroacetic acid, $0^{\circ} \mathrm{C}, 3 \mathrm{~h}, 80 \%$; d) Zn, ethyl-2-bromopropionate, $I_{2}$, ether, reflux, 3 h , then $\mathrm{H}^{+}, 80 \%$; e) $\mathrm{OsO}_{4}$ (cat), $\mathrm{NMO}, \mathrm{CH}_{3} \mathrm{CN}$ : $\mathrm{H}_{2} \mathrm{O}, 24 \mathrm{~h}, 95 \%$; f) pTSA, benzene, reflux, $1 \mathrm{~h}, 90 \%$ overall; g) $\mathrm{AlCl}_{3}, E t S H, \mathrm{CH}_{2} \mathrm{Cl}_{2}, r t, 12 \mathrm{~h}, 80 \%$.

Thus, enantiopure heritol has been synthesized enantiospecifically from naturally occurring $(R)-(+)$-citronellal, and absolute configuration of the naturally isolated (+)-heritol has been proposed.

Chapter-1 : Enantiospecific Synthesis of $\beta$-Herbertenol
Section-1 : Herbertenol: $\mathcal{A}$ Brief Review

### 1.1.1 Introduction

The unique plant group Liverworts contain several oil bodies characteristic of the species. Indeed in general, a significant biochemical characteristic of the liverworts (Hepaticae) is that they produce sesquiterpenoids metabolites, which are enantiomers of those compounds produced by the higher plants. Particularly, herbertous species is a rich source of Herbertene (iso-cuparene) type $\mathbf{1}$ as well as cuparene type $\mathbf{2}$ sesquiterpenoids. ${ }^{1-3}$

3f $R=C H O ; X=Y=O H ; Z=H$
3g $R=C O O M e ; X=Y=O H ; Z=H$

Isolation of the first members of the herbertane group; herbertene 3a, $\alpha$-herbertenol 3b, $\beta$-herbertenol 3c, herbertenediol 3d, herbertenal $\mathbf{3 e}$ and herbertenolide $\mathbf{4 a}$ from Herberta adunca was reported earlier by Matsuo ${ }^{1 \mathrm{~b}}$ and co-workers. Subsequently, Rycroft et al reported the isolation of the aldehyde $\mathbf{3 f}$ and the ester $\mathbf{3 g}$ from Herbertus aduncus. ${ }^{\text {1c }}$ The phenolic herbertanes, e. g., 3b-d have been shown to possess interesting biological properties ${ }^{1-3}$ such as growth inhibiting activity, antifungal, antilipid peroxidation and neurotropic activities. The dimeric herbertanes, mastigophorenes A and B ( $\mathbf{5 a}$ and $\mathbf{5 b}$ ), isolated ${ }^{2}$ along with their isomers, mastigophorenes $C$ and $D$, and herbertenols from the liverwort Mastigophora diclados, were shown to stimulate nerve growth. Recently, Asakawa ${ }^{1 d}$ and co-workers reported the isolation of seven new members of the herbertane group; herbertenelactol $\mathbf{4 b}$; 1,13-herbertenediol $\mathbf{6 ;}$ 1,14-herbertenediol 7; 1,15herbertenediol 8; herbertenones A (9a) and B (9b), and 12-methoxy herbertenediol $\mathbf{1 0}$ along with dimeric herbertanes (mastigophorenes A-C), from the Japanese liverworts Herberta sakuraii.

### 1.1.2 Total Synthesis of Herbertanes : A Review

The total synthesis of herbertanes as well as cuparene type sesquiterpenoids have attracted the attention of several synthetic organic chemists due to the difficulties associated with the construction of the vicinal quaternary carbons in the cyclopentane ring. However, despite their interesting biological properties, the phenolic herbertanes have received very little attention until recently. After 1999 only, several synthetic routes have been reported, which have been briefly reviewed here.

## Eicher's Approach : (Scheme-1 and 2, 1996) ${ }^{4}$

In this article, total synthesis of rac- $\alpha$-herbertenol $\mathbf{3 b}$, rac- $\beta$-herbertenol $\mathbf{3 c}$ and asymmetric synthesis of ent-herbertenolide, i. e. ent-4a using enzymatic resolution as the key step has been reported.

Scheme-1 : (Eicher et al, Synthesis 1996, 863-870)

Reagents and conditions : a) 4-methoxy-3-methylphenyl magnesium bromide, THF, $-40^{\circ} \mathrm{C}$ to rt , $77 \%$; b) $\mathrm{KHSO}_{4}, 140^{\circ} \mathrm{C}, 1 \mathrm{~h}, 99 \%$; c) (i) LAH, THF; (ii) $\mathrm{PCC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 48 \%$; d) $\mathrm{N}_{2} \mathrm{H}_{4}-\mathrm{H}_{2} \mathrm{O}, \mathrm{NaOH}$, DEG, $195{ }^{\circ} \mathrm{C}, 7 \mathrm{~h}, 50 \%$; e) (i) $\mathrm{NaBH}_{4}, \mathrm{BF}_{3}-\mathrm{OEt}_{2}$; (ii) $\mathrm{NaOH}, \mathrm{H}_{2} \mathrm{O}_{2}$; (iii) PCC, $\mathrm{NaOAc}, 43 \%$; f) $\mathrm{NaH}, \mathrm{MeI}, \mathrm{DME},-50^{\circ} \mathrm{C}$ to rt, $67 \%$; g) $\mathrm{N}_{2} \mathrm{H}_{4}-\mathrm{H}_{2} \mathrm{O}$, $\mathrm{NaOH}, \mathrm{DEG}, 220^{\circ} \mathrm{C}, 3 \mathrm{~d}, 45 \%$.

## Scheme-2

Reagents and conditions : a) baker's yeast, $\mathrm{H}_{2} \mathrm{O}$, glucose, $65 \%$; b) LDA, THF, MeI, HMPA, 84\%; c) $\mathrm{Na}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{Et}_{2} \mathrm{O}, 69 \%$.

The synthesis of rac-3c (Scheme-1) started from cyclopentanone derivative 11, which on Grignard addition followed by dehydration provided intermediate 13. It was further transformed to the dimethyl cyclopentene intermediate $\mathbf{1 5}$ in a few steps, which on hydroboration-oxidation and PCC oxidation in acetate buffer gave cyclopentanone 16 in
moderate yields. Further, intermediate 16 on methylation followed by Wolff-Kishner reduction provided the required rac-3c. Using similar strategy, rac-herbertenolide $\mathbf{4 a}$ and $r a c-\alpha$-herbertenol 3b have also been synthesized.

For the asymmetric synthesis of herbertenolide ent-4a, chiral $\beta$-keto ester (-)-1R-21 was used, which was obtained by baker's yeast reduction of rac-18, followed by diastereoselective methylation of the resultant chiral ester 19 and oxidation of the secondary hydroxyl group (Scheme-2).

## Fukuyama's Approach : (Scheme-3, 1996) ${ }^{5}$

This communication reported the first total synthesis of rac-herbertenediol 3d, which was proposed to be biosynthetic precursor of mastigophorenes $\mathbf{5}(\mathbf{a}, \mathbf{b})$. Here, they utilized intramolecular Heck reaction for the construction of quaternary carbon at the benzylic position of rac- $\alpha$-herbertenol $\mathbf{3 b}$, which was further transformed to rac-3d.

Scheme-3 : (Fukuyama et al, Tetrahedron Lett. 1996, 37, 1261-1264)

Reagents and conditions : a) (i) 2,4,6-Cl $\mathrm{C}_{3} \mathrm{C}_{2} \mathrm{COCl}, \mathrm{Et}_{3} \mathrm{~N}$, THF; (ii) 2-iodo-4-methylphenol, DMAP, benzene, 63\%; b) Pd (OAc) $)_{2}$, (o-Tol $)_{3} P, n-\mathrm{Bu}_{3} \mathrm{~N}, \mathrm{DMF}, 97 \%$; c) (i) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, \mathrm{EtOH}$; (ii) LAH, THF, 93\%; (iii) MeI, $\mathrm{K}_{2} \mathrm{CO}_{3}$, acetone; d) ( COCl$)_{2}, \mathrm{DMSO}, \mathrm{Et}_{3} \mathrm{~N}^{2} \mathrm{CH}_{2} \mathrm{Cl}_{2}, 89 \%$; e) (i) $\mathrm{N}_{2} \mathrm{H}_{4}$, $\mathrm{NaOH}, \mathrm{DEG}$; (ii) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 81 \%$; f) (i) MOMCl, i- $\mathrm{Pr}_{2} E t N, \mathrm{CH}_{2} \mathrm{Cl}_{2}$; (ii) s-BuLi, TMEDA, MoOPH, THF; (iii) HBr, MeOH, $88 \%$.

Thus, cyclopentene carboxylic acid rac-22 was treated with 2-iodo-4-cresol under Yamaguchi conditions to give an ester 23 in $63 \%$ yield, which on intramolecular Heck reaction provided lactone 24 in $97 \%$ yield as a mixture of double bond isomers. After hydrogenation of the double bond and a few functional group transformations, rac- $\alpha$ herbertenol 3b was obtained in high yields, which on hydroxylation by Vedejs ${ }^{\prime}{ }^{6}$ method and MOM ether deprotection afforded rac-herbertenediol 3d in $88 \%$ overall yield from 3b.

## Harrowven's Approach : (Scheme-4, 1998) ${ }^{7,8}$

Synthesis of rac- $\alpha$-herbertenol 3b reported by Harrowven et al featured the use of dihydropyranone as a 1,5 -diketone synthon.

Scheme-4 : (Harrowven et al, Tetrahedron Lett. 1998, 39, 9573-9574)

Reagents and conditions : a) $n$-BuLi, THF, $-78^{\circ} \mathrm{C}, 1 \mathrm{~h}$, then $28,-78^{\circ} \mathrm{C}, 15$ min, $\mathrm{TMSCl}, r \mathrm{rt}, 77 \%$; b) $\mathrm{TiCl}_{4}, \mathrm{Mg}, \mathrm{THF},-40^{\circ} \mathrm{C}, 1 \mathrm{~h}, 61 \%$; c) $\mathrm{Me}_{2} \mathrm{TiCl}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}, 24 \mathrm{~h}, 40 \%$; d) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}, 1$ h, rt, 16 h, $99 \%$.

Accordingly, organolithium reagent derived from 27 was treated with dihydropyranone 28, which on quenching with chorotrimethylsilane provided 1,5-diketone 29 in 77\% yield. Intramolecular Pinacol coupling reaction of diketone 29 induced by a low valent titanium resulted in diol $\mathbf{3 0}$, which was then converted to rac-3b through exposure to dimethyltitanium dichloride, followed by methyl ether deprotection of the resulting intermediate 31.

## Meyer's Approach : (Scheme-5, 1999) ${ }^{9}$

In this particular approach, a non-racemic bicyclic latam 37 has been utilized to construct a chiral cyclopentane containing vicinal quaternary carbon centers in optically pure form of (-)-herbertenediol 3d, which was further elaborated for asymmetric synthesis of (-)-mastigophorenes A 5a and B 5b.

Scheme-5 : (Meyer et al, J. Am. Chem. Soc. 1999, 121, 2762-2769)

Reagents and conditions : a) $\mathrm{HCHO}, \mathrm{Me}_{2} \mathrm{NH}, 100 \%$; b) (i) MeI; (ii) $\mathrm{KCN}, 90 \%$; c) (i) $\mathrm{Me}_{2} \mathrm{SO}_{4}$, PTC, $100 \%$; (ii) $\mathrm{NaOH}, \mathrm{MeOH}, \mathrm{H}_{2} \mathrm{O}, 97 \%$; d) (i) 2 equivalents LDA, rac-propyleneoxide; (ii) Swern oxidation, $80 \%$; e) (S)-valinol, benzene, 83\%; f) LDA, MeI, THF, -100 ${ }^{\circ} \mathrm{C}$, $85 \%$ (33: 1); g) Red-Al; h) (i) $\mathrm{KH}_{2} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{O}, \mathrm{EtOH}$; (ii) $\mathrm{KOH}, \mathrm{EtOH}, 84 \%$; i) NaH, MeI, DMF, 60\%; j) (i) ( $\left.\mathrm{ArPS}_{2}\right)_{2}$, toluene; (ii) Raney Ni, $\mathrm{H}_{2}, \mathrm{EtOH}, 58 \%$; (iii) $\mathrm{BBr}_{3}, 91 \%$.

Thus, phenol 32 was subjected to Mannich conditions to afford benzylamine 33, which was further quaternised and displaced by KCN to provide substituted phenyl acetonitrile 34 in high yields. Protection of phenol and alkaline hydrolysis of cyanide functionality gave phenylacetic acid $\mathbf{3 5}$ in almost quantitative yield. It's dianion was then quenched with propylene oxide to give $\gamma$-hydroxy acid, which was directly oxidized to afford the requisite ketoacid rac - $\mathbf{3 6}$ in $80 \%$ overall yield. It's condensation with ( S )-valinol gave bicyclic lactam 37 as a 3: 2 mixture of epimers, which on $C$-methylation using LDA as the base furnished a 33: 1 mixture of endo: exo diastereomers 38, which on reduction
with Red-Al followed by hydrolysis and base induced cyclisation of the resulting ketoaldehyde afforded chiral cyclopentenone 40 in $84 \%$ yield. This was further transformed to the required (-)-3d efficiently.

#### Abstract

Abad's Approach : (Scheme-6, 1999) ${ }^{10}$ This article described enantioselective synthesis of (-)- $\alpha$-herbertenol 3b and (-)herbertene 3a by adopting the chemistry developed previously by the same authors for the enantioselective synthesis of several cuparanes, ${ }^{11}$ where Katsuki-Sharpless asymmetric epoxidation was utilized for introduction of chirality.

Scheme-6 : (Abad et al, J. Org. Chem. 1999, 64, 1741-1744)

Reagents and conditions : a) $\mathrm{NaH}, \mathrm{BnBr}, 88 \%$; b) $\mathrm{SnCl}_{4}, 85 \%$; c) (i) NaHMDS; (ii) $\alpha$ trimethylsilyl vinyl ketone; (iii) $\mathrm{KOH}, 80 \%$; d) $\mathrm{KOH}, 120^{\circ} \mathrm{C}, 78 \%$; e) $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{CH}_{2}, 83 \%$; f) (i) $\mathrm{Pd} / \mathrm{C}$, $\mathrm{H}_{2}, \mathrm{EtOAc}$; (ii) $\left.\mathrm{Pd}, \mathrm{CaCO}_{3}, \mathrm{Pd}(\mathrm{OH})_{2} / \mathrm{C}, \mathrm{H}_{2}, \mathrm{EtOH} ; \mathrm{g}\right) \mathrm{TPAP}, \mathrm{NMO}, 84 \%$ from 47; h) $\mathrm{S}, 200^{\circ} \mathrm{C}$, $65 \%$.

Accordingly, enantiopure ( $1 S, 2 S$ )-epoxy alcohol 42 was prepared in $89 \%$ yield ( $98 \%$ ee) from readily available $\beta$-cyclogeraniol 41 by Katsuki-Sharpless asymmetric epoxidation. The hydroxy group of it was protected as it's benzyl ether 43, followed by Pinacol rearrangement using tin (IV) chloride in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at low temperature to afford $\alpha$ benzyloxy ketone $\mathbf{4 4}$ without loss of optical purity in $85 \%$ yield. The sodium enolate of $\mathbf{4 4}$
was then reacted with $\alpha$-trimethylsilyl vinyl ketone followed by treatment with KOH in MeOH , which afforded benzyloxy ketone 45 in $80 \%$ isolated yield. It was further treated with KOH in a sealed tube at $120^{\circ} \mathrm{C}$ for 6 h to furnish enone 46 in $78 \%$ yield, which on chemoselective hydrogenation followed by TPAP oxidation and finally aromatization using sulfur resulted in the requisite (-)- $\alpha$-herbertenol $\mathbf{3 b}$ in good yields.

Later in 2000, the same authors have reported enantioselective synthesis of $(-)-\alpha-$ formylherbertenol 3e using similar synthetic strategy. ${ }^{12}$

## Mukherjee's Appoach : (Scheme-7, 1999) ${ }^{13}$

The present communication dealt with the synthesis of rac-3b and other related herbertanes using $\alpha, \alpha$-dimethylation of the ester $\mathbf{5 3}$ as the key step.

Scheme-7 : (Mukherjee et al, Tetrahedron Lett. 1999, 40, 4733-4734)

Reagents and conditions : a) $\mathrm{CH}_{2}\left(\mathrm{CN}_{2}, \mathrm{NH}_{4} \mathrm{OAc}\right.$, AcOH, benzene, reflux, quantitative; b) MeMgI, CuI, THF, $25{ }^{\circ} \mathrm{C}$, then reflux, $89 \%$; c) (i) $\mathrm{KOH}, \mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}, \mathrm{H}_{2} \mathrm{O}$, reflux, $\mathrm{H}^{+}, 190{ }^{\circ} \mathrm{C}$; (ii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, 82 \%$; d) LDA, THF, $-20^{\circ} \mathrm{C}$, MeI, HMPA, $-78^{\circ} \mathrm{C}, 95 \%$; e) LDA, HMPA, THF, $0^{\circ} \mathrm{C}$, MeI, $92 \%$; f) $\mathrm{CrO}_{3}, \mathrm{AcOH}, 10-25^{\circ} \mathrm{C}, 75 \%$; g) mCPBA, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CF}_{3} \mathrm{COOH}, 0$ to $25^{\circ} \mathrm{C}, 84 \%$; h) (i) aq. $\mathrm{NaOH}, \mathrm{MeOH}$, reflux, $\mathrm{Me}_{2} \mathrm{SO}_{4}, \mathrm{H}^{+}$; (ii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, 85 \%$; i) (i) t-BuOK, benzene, reflux, $\mathrm{H}^{+}$, DMSO, $\mathrm{NaCl}, 150^{\circ} \mathrm{C}, 75 \%$; (ii) $\mathrm{N}_{2} \mathrm{H}_{4}, \mathrm{~N}_{2} \mathrm{H}_{4}-2 \mathrm{HCl}, \mathrm{DEG}, 130^{\circ} \mathrm{C}, \mathrm{KOH}, 210^{\circ} \mathrm{C}, 75 \%$; (iii) $\mathrm{BBr} r_{3}, 72 \%$.

Accordingly, tetralone $\mathbf{5 0}$ was condensed with malononitrile to provide unsaturated nitrile 51 in quantitative yield. Conjugate addition of MeMgI on $\mathbf{5 1}$ followed by hydrolysis, decarboxylation and esterification afforded ester 53 in $\mathbf{7 3} \%$ overall yield. The ester $\mathbf{5 3}$ was alkylated with MeI at $-78{ }^{\circ} \mathrm{C}$ using LDA (1 equivalent) as the base to provide ester $\mathbf{5 4}$ as a diastereomeric mixture, which was further alkylated with MeI in presence of LDA (1.7 equivalents) and HMPA (2 equivalents) at $0^{\circ} \mathrm{C}$ to afford ester 55 in $87 \%$ yield. After a few functional group transformations, the resultant diester $\mathbf{5 8}$ was subjected to Dieckmann cyclisation followed by decarboxylation of the resultant crude $\beta$-keto ester, which on Huang-Minlon reduction and demethylation furnished rac-3b.

Later in 2000, the same authors have reported syntheses of rac-herbertene 3a, rac-$\beta$-herbertenol 3c and rac-herbertenediol 3d using similar synthetic strategy. ${ }^{14}$

## Bringmann's Approach : (Scheme-8, 2000) ${ }^{15}$

An enantioselective synthesis of (-)-herbertenediol 3d has been described here, which is quite similar to Fukuyama's strategy ${ }^{5}$ for the synthesis of rac-3d.

Scheme-8 : (Bringmann et al, J. Am. Chem. Soc. 2000, 122, 9127-9133)

Reagents and conditions : a) (i) $\mathrm{NaBH}_{4}$; (ii) $\left(\mathrm{CBrCl}_{2}\right)_{2}, \mathrm{PPh}_{3}$; (iii) LAH, $82 \%$; b) 22, DCC, DMAP, $79 \%$; c) (i) $\mathrm{Pd}(\mathrm{OAc})_{2}$; (ii) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, 72 \%$; d) $\mathrm{BH}_{3}-\mathrm{THF}$, (S)-65, $-78^{\circ} \mathrm{C}, 46 \%$.

However, this synthesis differs in two respects : First, dioxygenated aromatic building block 59 has been used as a starting material, which was transformed to racemic lactone $\mathbf{6 2}$ using diastereoselective intramolecular Heck coupling of ester $\mathbf{6 1}$ as one of the key steps. And second, authors have developed a route to enantiomerically pure material, which was achieved by kinetic resolution of the lactone $\mathbf{6 2}$ by subjecting it to CBS reduction. Under these conditions, reduction was found to proceed with perfect enantiomer-differentiating selectivity, which afforded unreacted enantiomer ( $\boldsymbol{R}, \boldsymbol{R}$ )-64 in $99.9 \%$ ee after $51.5 \%$ conversion of the starting lactone 62. This was further utilized for the synthesis of (-)-3d as reported earlier. ${ }^{5}$

## Fukuyama's Approach : (Scheme-9, 2001) ${ }^{16,17}$

This article entitled "Total syntheses of neuroprotective mastigophorenes A and B" reported enantioselective synthesis of (-)-herbertenediol 3d by applying intramolecular Heck reaction as the key step as described earlier, except starting from $(R)$-carboxylic acid 69, which was prepared by using Koga's protocol ${ }^{18}$ as shown below.

Scheme-9 : (Fukuyama et al, Tetrahedron 2001, 57, 7127-7135)

Reagents and conditions : a) (S)-valine tert-butylester, BF $_{3}$-OEt ${ }_{2}$, benzene, 99\%; b) LDA, HMPA, MeI, $-78^{\circ} \mathrm{C}$, then $-25^{\circ} \mathrm{C}$, toluene, $40 \%$ ( $98 \%$ ee ); c) (i) MeMgI, $E t_{2} \mathrm{O}$; (ii) $\mathrm{P}_{2} \mathrm{O}_{5}$, benzene; (iii) KOH , $\mathrm{MeOH}, \mathrm{H}_{2} \mathrm{O}$, $33 \%$ for 3 steps.

Accordingly, lithiated chiral enamine 67, prepared from methyl-2-oxo-cyclopentane carboxylic acid 66 and ( $S$ )-valine tert-butyl ester, was alkylated with MeI in toluene containing HMPA to give ( $\boldsymbol{R}$ )-68, which was transformed to ( $\boldsymbol{R}$ )- $\mathbf{6 9}$ following a few steps. (-)-Herbertenediol 3d, thus synthesized from ( $\boldsymbol{R}$ )-69, was further utilized for the synthesis of (-)-mastigophorenes A and B.

Srikrishna's Approach : (Scheme-10, 2001) ${ }^{19,20}$
Claisen rearrangement based formal synthesis of rac-herbertenediol 3d reported by Srikrishna et al started from vanillin 70, which was subjected to Clemmensen reduction followed by $O$-allylation to furnish allyl ether 72.

Scheme-10 : (Srikrishna et al, Tetrahedron Lett. 2001, 42, 5781-5782)

Reagents and conditions : a) $\mathrm{K}_{2} \mathrm{CO}_{3}$, acetone, allylbromide, reflux, $92 \%$; b) sealed tube, $180^{\circ} \mathrm{C}$, $67 \%$; c) $\mathrm{NaOH}, \mathrm{Me}_{2} \mathrm{SO}_{4}, 87 \%$; d) $\mathrm{O}_{3}, \mathrm{O}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{MeOH},-70{ }^{\circ} \mathrm{C}, \mathrm{Me}_{2} \mathrm{~S}, r t$; e) Jones' reagent, acetone, $0^{\circ} \mathrm{C}$ to rt, MeOH, $\mathrm{H}_{2} \mathrm{SO}_{4}, 94 \%$; f) LDA, THF, MeI, $-70^{\circ} \mathrm{C}$ to rt, $88 \%$; g) LDA, THF, HMPA, allylbromide, $-70^{\circ} \mathrm{C}$ to rt, $74 \%$; h) (i) LAH, Et O ; (ii) PCC, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 87 \%$; i) $\mathrm{PdCl}_{2}$, $\mathrm{CuCl}, \mathrm{DMF}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}, r t, 77 \%$; j) KOH, MeOH, THF, rt, $92 \%$; k) (i) NaH, THF, DMF, MeI, rt, 76\%; (ii) Pd/C, $\mathrm{H}_{2}$, EtOH, rt, 1 atm., 95\%; (iii) ref-9.

Thermal activation of $\mathbf{7 2}$ at $180{ }^{\circ} \mathrm{C}$ afforded ortho Claisen product $\mathbf{7 3}$ in $67 \%$ yield, which was transformed to ester $\mathbf{7 6}$ in a few steps. Alkylation of the ester $\mathbf{7 6}$ with MeI using LDA as the base generated the ester 77, which on further allylation with allyl bromide using LDA, HMPA furnished the key intermediate 78. A two step conversion of the ester to an aldehyde and Wacker oxidation of the terminal olefin, followed by intramolecular
aldol condensation of the resultant keto-aldehyde $\mathbf{8 0}$, resulted in the cyclopentenone $\mathbf{8 1}$ in $61 \%$ overall yield. It was further utilized for the synthesis of the title compound.

## Abad's Approach : (Scheme-11, 2001) ${ }^{21}$

An approach for the construction of the bicyclic herbertane system based on a Suzuki cross coupling reaction ${ }^{22}$ and a [2,3]-sigmatropic Still-Wittig rearrangement ${ }^{23}$ has been described here, which culminated in the synthesis of rac-herbertenediol 3d.

Scheme-11 : (Abad et al, Tetrahedron 2001, 59, 9727-9735)

90

$$
g\left\{\begin{array}{l}
91 \mathrm{R}=\mathrm{H}, \mathrm{OH} \\
92 \mathrm{R}=\mathrm{O}
\end{array}\right.
$$

$\underline{\text { Reagents and conditions : a) } P d\left(P_{P h}\right)_{4}, ~ a q . ~} \mathrm{Na}_{2} \mathrm{CO}_{3}$, dioxane, reflux, 98\%; b) $P d_{2}(d b a)_{3}, N M P, r t$, 60\%; c) DIBAL, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}, 98 \%$; d) KH, THF, $0^{\circ} \mathrm{C}, \mathrm{Me}_{3} \mathrm{SnCH}_{2} \mathrm{I}$, rt, $95 \%$; e) n-BuLi, hexane, $-78{ }^{\circ} \mathrm{C}$ to $-10{ }^{\circ} \mathrm{C}, 55 \%$; f) $\mathrm{Et}_{2} \mathrm{Zn}, \mathrm{CH}_{2} \mathrm{I}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 76 \%$; g) Swern oxidation, $85 \%$; h) (i) $\mathrm{N}_{2} \mathrm{H}_{4}$, DEG, $\mathrm{NaOH}, 160^{\circ} \mathrm{C}, 75 \%$; (ii) $\mathrm{H}_{2}, \mathrm{PtO}_{2}, \mathrm{AcOH}, \mathrm{NaOAc}, 80 \%$; (iii) $\mathrm{BBr}_{3}, 82 \%$.

Thus, Suzuki cross coupling of the aryl boronic acid $\mathbf{8 3}$ with the enoltriflate $\mathbf{8 2}$ afforded the enone 85 in very high yield, which on DIBAL reduction at $-78^{\circ} \mathrm{C}$ gave allyl alcohol $\mathbf{8 6}$ in $98 \%$ yield. For the construction of the quaternary benzylic carbon, the alcohol 86 was transformed to the allylstannyl methyl ether 87, which on treatment with n-BuLi at $-78{ }^{\circ} \mathrm{C}$ generated the $\alpha$-lithio ether, that underwent a smooth [2,3]-sigmatropic
rearrangement upon warming to $-10{ }^{\circ} \mathrm{C}$ to deliver the homoallylic alcohol 90 in $55 \%$ overall yield, together with 3: 2 mixture of allylic alcohol $\mathbf{8 8}$ and a small amount of methyl ether 89. Intermediate $\mathbf{9 0}$ on cyclopropanation followed by Swern oxidation of the primary hydroxyl group afforded 92, which on Huang-Minlon reduction, reductive opening of the cyclopropane ring and demethylation furnished rac-herbertenediol 3d.

## Srikrishna's Approach : (Scheme-12, 2002) ${ }^{24}$

The second communication by Srikrishna et al described total synthesis of rac-1,14-herbertenediol 7 and epi-herbertenolide, i. e. 11-epi-4a using ring closing metathesis as the key step.

Scheme-12 : (Srikrishna et al, Tetrahedron Lett. 2002, 43, 151-154)

Reagents and conditions : a) (i) $\mathrm{NaH},(E t \mathrm{O})_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{COOEt}, \mathrm{THF}, \mathrm{rt}, 16 \mathrm{~h}$; (ii) LAH, $\mathrm{Et}_{2} \mathrm{O},-70$ ${ }^{\circ} \mathrm{C}$ to $\mathrm{rt}, 2 \mathrm{~h}, 87 \%$; b) $\mathrm{MeC}(\mathrm{OEt})_{3}, \mathrm{EtCOOH}, 180^{\circ} \mathrm{C}, 76 \%$; c) LDA, THF, $-70^{\circ} \mathrm{C}$ to rt, allylbromide, $4 \mathrm{~h}, 86 \%$; d) Grubbs' catalyst, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, $4 \mathrm{~h}, 95 \%$; e) LDA, THF, HMPA, $0^{\circ} \mathrm{C}$ to $\mathrm{rt}, \mathrm{MeI}, 77 \% ;$ f) (i) $\mathrm{Pd} / \mathrm{C}, \mathrm{H}_{2}, \mathrm{EtOH}, r t, 93 \%$; (ii) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to $\mathrm{rt}, 85 \%$; g) $\mathrm{LAH}, \mathrm{Et}_{2} \mathrm{O},-70^{\circ} \mathrm{C}$ to $\mathrm{rt}, 92 \%$.

The synthesis of rac-7 started from acetophenone 93, which on Horner-WadsworthEmmons olefination followed by regioselective reduction of the ester functionality with LAH provided key intermediate 94. The orthoester Claisen rearrangement of this allylic
alcohol 94 using triethylorthoacetate and propionic acid in a sealed tube at $180{ }^{\circ} \mathrm{C}$ furnished the ester 95 , which on $C$-allylation followed by ring closing metathesis of the resulting diene ester $\mathbf{9 6}$ provided 97 . It was further transformed to the title compound as depicted in the scheme- 12 .

## Mukherjee's Approach : $\left(\right.$ Scheme-13, 2003) ${ }^{25}$

Stereoselective synthesis of rac- $\alpha$-herbertenol 3b, rac- $\beta$-herbertenol $\mathbf{3 c}$ and rac-1,4cuparenediol 107 have been described involving intramolecular cyclisation of 3-aryl-3-methyl-6-bromohexanoates $\mathbf{1 0 4}$ and in situ methylation of the resulting cyclopentane carboxylate as the key steps. The reaction sequence has been depicted in the following scheme.

Scheme-13 : (Mukherjee et al, Tetrahedron Lett. 2003, 44, 737-740)

$$
\left[\begin{array}{l}
\text { For } 100 \text { to } 106 \\
R_{1}=O M e, R_{2}=H, R_{3}=M e \text { or } \\
R_{1}=H, R_{2}=O M e, R_{3}=M e \text { or } \\
R_{1}=R_{3}=O M e, R_{2}=M e
\end{array}\right]
$$

Reagents and conditions : a) $\mathrm{CH}_{2}(\mathrm{CN}) \mathrm{COOEt}, \mathrm{NH}_{4} \mathrm{Ac}, \mathrm{AcOH}$, benzene, reflux, $75 \%$; b) ($\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{O}-\mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{MgBr}, \mathrm{CuBr}-\mathrm{Me}_{2} \mathrm{~S}$, THF, $\mathrm{Et}_{2} \mathrm{O}, 0$ to $20^{\circ} \mathrm{C}, 58 \%$; c) (i) KOH , ethylene glycol, $\mathrm{H}_{2} \mathrm{O}$, reflux, $\mathrm{AcOH}, 0^{\circ} \mathrm{C}$; (ii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, 0^{\circ} \mathrm{C}, 75 \%$; d) (i) $\mathrm{AcOH}-\mathrm{H}_{2} \mathrm{O}, 25$ to $60^{\circ} \mathrm{C}$; (ii) $\mathrm{NaBH}_{4}$, MeOH, 0 to $25^{\circ} \mathrm{C}$, $82 \%$; e) $\mathrm{PBr}_{3}$, benzene, 0 to $70^{\circ} \mathrm{C}$, $85 \%$; f) (i) LDA, THF, HMPA, $-70^{\circ} \mathrm{C}$; (ii) LDA, HMPA, THF, $0^{\circ} \mathrm{C}$, MeI, 85\%; g) (i) LAH, THF, reflux, 85\%; (ii) PCC, NaOAc, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 25$ ${ }^{\circ} \mathrm{C}, 85 \%$; h) (i) $\mathrm{N}_{2} \mathrm{H}_{4}, \mathrm{~N}_{2} \mathrm{H}_{4}-2 \mathrm{HCl}, \mathrm{DEG}, 125^{\circ} \mathrm{C}$, KOH, $210^{\circ} \mathrm{C}$; (ii) $\mathrm{BBr}_{3}, 70 \%$.

Srikrishna'a Approach : $\left(\right.$ Scheme-14, 2003) ${ }^{26}$
This particular approach resembles the previous one by Srikrishna et al in involvement of Claisen rearrangement and RCM as the key reactions.

Scheme-14 : (Srikrishna et al, Tetrahedron Lett. 2003, 44, 1027-1030)

Reagents and conditions : a) Li, THF, ))), 45 min, 72 and 79\%; b) PCC, silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 91$ and $89 \%$; c) vinyl magnesium bromide, THF, 78 and $80 \%$; d) (i) PCC, silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 84$ and $76 \%$; (ii) $\mathrm{NaBH}_{4}, \mathrm{MeOH}, 0-5{ }^{\circ} \mathrm{C}, 89$ and $81 \%$; e) $\mathrm{MeC}(\mathrm{OEt})_{3}$, EtCOOH, sealed tube, $180^{\circ} \mathrm{C}, 30$ and $45 \%$; f) $\mathrm{PhCH}=\mathrm{RuCl}_{2}\left(\mathrm{PCy}_{3}\right)_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 88$ and $94 \%$.

Scheme-14 represents the reaction sequence using which rac- $\alpha$-herbertenol 3b and rac- $\beta$-herbertenol $3 \mathbf{c}$ have been synthesized.

Kita's Approach : (Scheme-15, 2003) ${ }^{27}$
This communication described asymmetric synthesis of (-)-herbertenediol 3d using rearrangement of the optically active 3-aryl-2-methyl-2,3-epoxytosylate $\mathbf{1 1 9}$ ( $98 \%$ ee), which was synthesized from pentanedione $\mathbf{1 1 6}$ using CBS reduction and stereoselective epoxidation as the key steps.

Scheme-15 : (Kita et al, Tetrahedron Lett. 2003, 44, 411-413)

Reagents and conditions : a) (i) TsOH, i-BuOH; (ii) 2,3-dimethoxy-5-methyl bromobenzene, $n$ BuLi, $\mathrm{CeCl}_{3}$; b) $\mathrm{BH}_{3}-\mathrm{Me}_{2} \mathrm{~S}, 65,100 \%$; c) (i) VO(acac) ${ }_{2}$, TBHP, 99\%; (ii) TsCl, pyridine, $100 \%$; d) $\mathrm{EtAlCl}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, ~ 99 \%$; e) $\mathrm{Zn}, \mathrm{AcOH}, 91 \%$; f) $\mathrm{MeLi}, \mathrm{CeCl}_{3}, \mathrm{THF}, 92 \%$; g) $\mathrm{EtN}^{+} \mathrm{SO}_{2} \mathrm{NCOOMe}$, THF, reflux, $82 \%$; h) $\mathrm{Et}_{2} \mathrm{Zn}, \mathrm{CH}_{2} \mathrm{I}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 76 \%$; i) $\mathrm{PtO}_{2}, \mathrm{H}_{2}, \mathrm{NaOAc}, \mathrm{AcOH}, 93 \%$; j) $\mathrm{BBr}_{3}, 93 \%$.

Thus, epoxide 119 ( $98 \%$ ee) on treatment with $\mathrm{EtAlCl}_{2}$ afforded rearranged product 120 in high yield and without loss of optical purity. Reductive removal of the tosyloxy group followed by 1,2 -addition of $\mathrm{MeCeCl}_{2}$ gave alcohol $\mathbf{1 2 2}$, which on dehydration using Burgess reagent followed by cyclopropanation of the resulting cyclopentene $\mathbf{1 2 3}$ under Simmons-Smith conditions, provided 124. The reductive opening of the cyclopropane ring of $\mathbf{1 2 4}$ followed by demethylation furnished (-)-3d ( $98 \% \mathrm{ee}$ ). Similar strategy has also been employed for the enantioselective synthesis of ( - )- $\alpha$-herbertenol $\mathbf{3 b} .^{28}$

## Chavan's Approach : (Scheme-16, 2003) ${ }^{29}$

This article described synthesis of rac- $\beta$-herbertenol 3c using 1,3-cyclopentadione annelation strategy ${ }^{30}$ for the introduction of quaternary benzylic methyl group.

Scheme-16 : (Chavan et al, Tetrahedron 2003, 59, 2737-2741)

Reagents and conditions : a) $\mathrm{BF}_{3}-\mathrm{OEt}_{2},-78^{\circ} \mathrm{C}, 68 \%$; b) $\mathrm{Ph}_{3} \mathrm{P}^{+} \mathrm{MeI}$, KOBu-tert, benzene, reflux, $72 \%$; c) (i) $\mathrm{NaBH}_{4}, \mathrm{EtOH}, 98 \%$; (ii) BMS, THF, $0^{\circ}{ }^{\circ} \mathrm{C}$ to rt , then $\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{OH}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 71 \%$; d) (i) $\mathrm{Me}_{3} \mathrm{CCOCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to rt, $84 \%$; (ii) NaH, CS 2, THF, rt, MeI, $86 \%$; e) TBTH, AIBN, toluene, reflux, $83 \%$; f) (i) LAH, THF, $r$ t, $92 \%$; (ii) PCC, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 86 \%$; g) $\mathrm{NaH}, \mathrm{DME}, 0$ ${ }^{\circ} \mathrm{C}$, MeI, rt, $65 \%$; h) (i) $\mathrm{N}_{2} \mathrm{H}_{4}-\mathrm{H}_{2} \mathrm{O}, \mathrm{NaOH}, \mathrm{TEG}, 195^{\circ} \mathrm{C}, 52 \%$; (ii) $\mathrm{BBr}_{3}, 81 \%$.

Thus, cyclopenta-1,3-dione $\mathbf{1 2 7}$ was prepared by annelation of 1,3-dioxolane $\mathbf{1 2 5}$ and 1,2-disilyloxycyclobutene 126, which was further elaborated to the title compound using common functional group transformations in 4.5\% overall yield (Scheme-16).

## Srikrishna's Approach : (Scheme-17, 2004) ${ }^{31}$

The present approach dealt with the stereoselective synthesis of (+)- $\alpha$-herbertenol, $i$. e. ent-3b using Claisen rearrangement of the aryl allyl ether $\mathbf{1 3 6}$ as the key step. This aryl allyl ether $\mathbf{1 3 6}$ was prepared from allylalcohol $\mathbf{1 3 5}$, which in turn was synthesized in three steps from ( $R$ )-limonene $\mathbf{1 3 4}$. ${ }^{32}$

Scheme-17 : (Srikrishna et al, Tetrahedron 2004, 60, 2125-2130)

Reagents and conditions : a) p-cresol, $\mathrm{PPh}_{3}$, DIAD, THF, $r t, 85 \%$; b) PhNMe $e_{2}$, sealed tube, 180 ${ }^{\circ} \mathrm{C}, 65 \%$; c) $\mathrm{O}_{3} / \mathrm{O}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}-\mathrm{MeOH},-70{ }^{\circ} \mathrm{C}, \mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}$, benzene, reflux, $75 \%$; d) $\mathrm{K}_{2} \mathrm{CO}_{3}$, $\mathrm{MeOH}, r t, 83 \%$; e) PCC, $\mathrm{NaOAc}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, r t, 88 \%$; f) Li, liquid $\mathrm{NH}_{3}, 83 \%$.

Thus, thermal activation of the ether 136 in $N, N$-dimethylaniline in a sealed tube at $180{ }^{\circ} \mathrm{C}$ afforded 3: 5 mixture of the cyclised product $\mathbf{1 3 7}$ and $\mathbf{1 3 8}$ in $65 \%$ overall yield, which were separated by silica gel and silver nitrate impregnated silica gel column chromatography. After creating the requisite new chiral quaternary carbon atoms, the original chiral center was disposed off via degradation of the isopropenyl group employing a Criegee rearrangement ${ }^{33}$ to afford $\mathbf{1 3 9}$ in $75 \%$ yield. Hydrolysis of the acetate functionality of $\mathbf{1 3 9}$ and PCC oxidation of the resulting alcohol afforded ketone $\mathbf{1 4 0}$, which on reductive cleavage using Li in liquid $\mathrm{NH}_{3}$ furnished the diol intermediate 141. It was further elaborated to (+)- $\alpha$-herbertenol ent-3b in a few steps.

## Acherar's Approach : (Scheme-18, 2004) ${ }^{34}$

An enantioselective synthesis of (+)-1,14-herbertenediol 7, employing a lipase promoted kinetic resolution ${ }^{35}$ of $( \pm) \mathbf{- 1 4 4}$ as the key step, has been described in this particular approach.

Scheme-18 : (Acherar et al, Eur. J. Org. Chem. 2004, 5092-5099)

Reagents and conditions : a) (i) 2-bromo-4-methylanisole, $\mathrm{Mg}, \mathrm{Et}_{2} \mathrm{O}$; (ii) $\mathrm{ZnCl}_{2}$, THF, $0^{\circ} \mathrm{C}$; (iii) $\mathrm{Ni}(\text { acac })_{2}, \mathrm{THF}, 0^{\circ} \mathrm{C}, 96 \%$; b) $\mathrm{NaBH}_{4}, \mathrm{CeCl}_{3}-7 \mathrm{H}_{2} \mathrm{O}, \mathrm{EtOH},-78{ }^{\circ} \mathrm{C}$, quantitative; c) lipase AK , vinylacetate, $r$ t, $2 d, 53 \%$ (145) and $45 \%$ (146); d) $\mathrm{Na}_{2} \mathrm{CO}_{3}, \mathrm{MeOH}, r t, 97 \%$; e) (i) $\mathrm{NaH}, \mathrm{CS}_{2}, \mathrm{MeI}$, THF; (ii) TBTH, AIBN, toluene, reflux, $98 \%$; f) LDA, HMPA, MeI, THF, -90 ${ }^{\circ}$ C to rt, $65 \%$; g) (i) $\mathrm{BBr}_{3}$; (ii) LAH, $\mathrm{Et}_{2} \mathrm{O}, 0^{\circ} \mathrm{C}, 96 \%$.

The alcohol 144 was prepared by $\mathrm{Ni}(\text { acac })_{2}$-catalyzed 1,4 -addition of the organozinc reagent, prepared from 2-methoxy-5-methylphenylmagnesium bromide followed by Luche reduction of the resulting intermediate 143, in $96 \%$ overall yield. The acetate (+)-146 obtained after resolution, was hydrolyzed under alkaline conditions and the resultant secondary hydroxyl group of $\mathbf{1 4 7}$ was deoxygenated under Barton-McCombie's conditions, followed by stereoselective methylation of the resulting intermediate $\mathbf{1 4 8}$ using LDA as the base to provide the single diastereomer $\mathbf{1 4 9}$, which was further transformed to (+)-7 by deprotection of methyl ether and reduction of the ester functionality in high yields. Intermediate 149 was also utilized for the synthesis of (-)- $\alpha$-herbertenol 3b.

Srikrishna'a Approach : (Scheme-19, 2005) ${ }^{36}$
This communication reported a combination of Ireland ester Claisen rearrangement and RCM as the key steps for the formal synthesis of rac-herbertene-1,13-diol $\mathbf{6}^{37}$ and rac-$\alpha$-herbertenol 3b.

Scheme-19 : (Srikrishna et al, Synlett 2005, 7, 1173-1175)

Reagents and conditions : a) $\mathrm{O}_{3} / \mathrm{O}_{2}, \mathrm{MeOH}-\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{NaHCO}_{3},-70{ }^{\circ} \mathrm{C}, \mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}$, benzene, DMAP, reflux, $70 \%$; b) LDA, THF, allylbromide, $-70^{\circ} \mathrm{C}$ to $\mathrm{rt}, 85 \%$; c) $\mathrm{NaOH}, \mathrm{MeOH}-\mathrm{H}_{2} \mathrm{O}$, reflux, $95 \%$; d) DCC, DMAP, $\mathrm{Me}_{2} \mathrm{C}=\mathrm{CHCH}_{2} \mathrm{OH}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 92 \%$; e) (i) LDA, THF, TMSCl, $\mathrm{Et}_{3} \mathrm{~N},-70^{\circ} \mathrm{C}$ to rt, reflux; (ii) dilute HCl ; (iii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, 77 \%$; f) (i) $\mathrm{Cl}_{2} \mathrm{Ru}\left(\mathrm{PCy}_{3}\right)_{2}=\mathrm{CHPh}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 98 \%$; (ii) $\mathrm{Pd} / \mathrm{C}$, $\mathrm{H}_{2}, \mathrm{EtOH}, 1 \mathrm{~atm}, 100 \%$; g) LAH, $\mathrm{Et}_{2} \mathrm{O}, 97 \%$; h) PCC, silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 90 \%$.

The synthetic sequence started from anisole 150, which on ozonolysis followed by Criegee rearrangement and $C$-allylation of the resulting ester 151, afforded 152 in high yields. Further, dimethylallyl ester 154, prepared by DCC coupling reaction of the acid $\mathbf{1 5 3}$ and the corresponding allyl alcohol, on Ireland ester Claisen rearrangement followed by hydrolysis and esterification using diazomethane gave ester 155 in $77 \%$ yield. This diene ester $\mathbf{1 5 5}$ on ring closing metathesis using Grubbs' first generation catalyst followed by hydrogenation afforded 156, which was further transformed to the known aldehyde $\mathbf{1 5 8}$ in good yields and further converted to rac-3b efficiently.

Chapter-1, Section-2 : Enantiospecific Synthesis of (+)- $\beta$-Herbertenol

### 1.2.1 Introduction

Keeping in mind; (i) the biological activities associated with the phenolic herbertanes and (ii) abundancy of ( $R$ )-(+)-citronellal in both plants and of synthetic origin, prompted it's utilization for the first enantiospecific synthesis of laevigatin; ${ }^{1}$ which encouraged the design of enantiospecific synthesis of $\beta$-herbertenol $\mathbf{1},{ }^{2}$ that could be applicable to other herbertanes also. Here, the primary focus was just to introduce chirality at the nonfunctionalised benzylic position using ( $R$ )-(+)-citronellal as the source of chirality for herbertane skeleton formation, i. e. synthesis of cyclopentane ring with vicinal quaternary carbons. Thus, this section describes the first enantiospecific synthesis of $\beta$-herbertenol, where Taber's
 protocol of diazodecomposition of C-H insertion was used as the key step.

In 1982, Taber $^{3}$ reported a simple method for the preparation of 2-carbalkoxy cyclopentanones by intramolecular C-H insertion under Rh-catalyzed diazodecomposition of $\alpha$-diazo- $\beta$-ketoesters $\mathbf{2}$. The functionalized cyclopentanones produced by this cyclisation were proved to be versatile intermediates for elaboration of complex natural products. ${ }^{4}$

## Scheme-1

However, initial studies described in this publication didn't give any evidence of the proposed stereospecificity of C-H insertion process, but it was lateron proved by the same authors in 1985 by successfully applying it to the enantioselective synthesis of (+)- $\alpha-$ cuparenone $8,{ }^{5}$ where corresponding $\alpha$-diazo- $\beta$-ketoester 6 was synthesized by diastereoselective alkylation of oxazolidene $\mathbf{4}$ followed by a few functional group transformations.

Scheme-2 : (Taber et al, J. Am. Chem. Soc. 1985, 107, 196-199)

7
8

Reagents and conditions : a) LDA, THF, MeI, 49\%; b) $\mathrm{Rh}_{2}(\mathrm{OAc})_{4}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 52 \%$; c) ethylene glycol, p-TsOH; d) DIBAL; e) $\mathrm{HCl}, \mathrm{H}_{2} \mathrm{O}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, silica gel; f) L-Selectride, MeI, $26 \%$.

Intermediate 6 was further subjected to diazodecomposition by using $\mathrm{Rh}_{2}(\mathrm{OAc})_{4}$ as the catalyst to furnish cyclic $\beta$-ketoester 7, which on reductive alkylation resulted in $(+)-\alpha-$ cuparenone 8 ( $96 \%$ ee).

### 1.2.2 Present work : Results and discussion

Thus, as shown in the retrosynthetic analysis (Scheme-3), $\beta$-herbertenol $\mathbf{1}$ could be synthesized from cyclic $\beta$-ketoester 9 , which in turn could be obtained from acyclic $\alpha$ -diazo- $\beta$-ketoester $\mathbf{1 0}$ by using Taber's protocol of stereospecific C-H insertion by diazodecomposition. The corresponding $\beta$-ketoester could be synthesized from the anisole 11, which in turn could be synthesized enantiospecifically from ( $R$ )-(+)-citronellal via enone 12.

## Scheme-3

Accordingly, the synthesis initiated from enone 12, which was prepared from $(R)$ -$(+)$-citronellal as reported in the literature. ${ }^{6}$

## Scheme-4

Reagents and conditions : a) piperidine acetate, formalin, $110^{\circ} \mathrm{C}, 4 \mathrm{~h}$; b) methyl-2-methyl-3oxobutanoate, NaOMe (cat), MeOH, rt, 2 h, reflux, 5 h, $36 \%$.

The product formation was confirmed by comparison of it's IR and NMR spectral data with those of literature values ${ }^{6}$ and were found to be in good agreement with the proposed structure 12. Also, enone $\mathbf{1 2}$ was found to be a mixture of diastereomers as suggested by it's NMR spectral data, but as these newly generated chiral centers would be destroyed in the subsequent steps of the synthesis, no attempt was made to separate or characterize them.

The next crucial reaction was the aromatization of enone 12, for which dehydrohalogenation of the corresponding bromoenone $\mathbf{1 5}$ was envisioned as the key reaction. However, presence of an additional olefin functionality in the system forced us to opt for a method, which would provide selectivity and regiospecificity as well, in bromination of enone 12. This was achieved by adopting Hassner's protocol, ${ }^{7}$ where silyl enol ethers, derived from the corresponding aldehydes or ketones, were treated with 1 equivalent of NBS to afford the corresponding $\alpha$-bromo carbonyl compounds. This methodology is applicable to a wide range of carbonyl compounds; particularly noteworthy is the bromination in the presence of an olefin or ester functionality. Also, as one can regiospecifically synthesize enol ethers, ${ }^{8}$ this method would provide the required regiospecificity.

Accordingly, silyl enol ether $\mathbf{1 4}$ was prepared from enone $\mathbf{1 2}$ following the method developed by House et al, ${ }^{8}$ that is by treatment of $\mathbf{1 2}$ with LDA as the base to generate the enolate, which was quenched by chlorotrimethylsilane (silylating agent). Sily enol ether 14 on treatment with $N$-bromosuccinimide in THF at $0{ }^{\circ} \mathrm{C}$ afforded the bromoenone 15 (mixture of diastereomers) as the sole product in $40 \%$ isolated yield after column purification (Scheme-5). The poor yield might be attributed to the unstability of the bromoenone 15, which was characterized by it's NMR spectral data and was confirmed by it's mass spectrum, which exhibited a peak at $301(\mathrm{M}+2)^{+}$.

## Scheme-5

Reagents and conditions : a) LDA, THF, $-78{ }^{\circ} \mathrm{C}, 1.5 \mathrm{~h}, \mathrm{TMSCl},-78^{\circ} \mathrm{C}$ to $\mathrm{rt}, 5 \mathrm{~h}$; b) NBS, THF, 0 ${ }^{\circ} \mathrm{C}$, 30 min ; c) $\mathrm{Li}_{2} \mathrm{CO}_{3}, \mathrm{LiBr}, \mathrm{DMF}, 130-140{ }^{\circ} \mathrm{C}, 4 \mathrm{~h}, 75 \%$ overall; d) $\mathrm{Me}_{2} \mathrm{SO}_{4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$, acetone, reflux, $12 h, 90 \%$.

However, unstability associated with $\mathbf{1 5}$ necessitated to go for dehydrohalogenation without it's column purification, which was achieved by heating it with lithium carbonate
and lithium bromide in dry DMF at $130{ }^{\circ} \mathrm{C}$ and as anticipated, it furnished the requisite phenol derivative 16 in improved overall yield (75\%) from 12 (Scheme-5).

IR spectrum of the product $\mathbf{1 6}$ indicated the presence of a phenolic hydroxyl group by revealing an absorption at $3416 \mathrm{~cm}^{-1}$, further evident from a resonance at $\delta 151.7$ (s) in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Also, presence of three olefin protons in the olefin region of it's ${ }^{1} \mathrm{H}$ NMR spectrum; apart from one at $\delta 5.07(\mathrm{t}, J=6.8 \mathrm{~Hz})$, which corresponds to the side chain olefin proton; suggested the formation of $\mathbf{1 6}$. Further, three proton singlet at $\delta 2.23$, assigned to the methyl group attached to the aromatic ring, supported this. Other significant signals in it's ${ }^{1} \mathrm{H}$ NMR spectrum were : three proton doublet at $\delta 1.19(J=6.8 \mathrm{~Hz})$, assigned to the only secondary methyl group and two singlets at $\delta 1.52$ and 1.67 , each integrating for three protons, assigned to the two vinylic methyl groups. It's mass spectrum revealed a peak of $\left(\mathrm{M}^{+}\right)$at 218 , thus confirming the phenol derivative $\mathbf{1 6}$, which was finally ascertained by it's elemental analysis.

Phenol 16 was then protected as it's methyl ether 11 in $90 \%$ yield, using dimethyl sulfate and potassium carbonate in refluxing acetone (Scheme-5). Absence of absorption at $3416 \mathrm{~cm}^{-1}$ in it's IR spectrum and presence of a three proton singlet at $\delta 3.82$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum, characteristic of a methoxy group, suggested the formation of methyl ether derivative 11, which was further evident from an additional methyl resonance at $\delta 55.1$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Mass spectrum finally confirmed $\mathbf{1 1}$ by exhibiting a peak of (M$1)^{+}$at 231.

Having successfully synthesized the requisite aromatic unit 11, the key intermediate $\alpha$-dizo- $\beta$-ketoester 10 could be obtained via an acid intermediate 17, for which side chain double bond of $\mathbf{1 1}$ should be oxidatively chopped off. For this purpose, Weinrebs' protocol ${ }^{9}$ was adopted, which uses combination of catalytic amount of osmium tetroxide and stoichiometric amount of Jones' reagent in acetone. It is believed that the process involves initial formation of an osmate ester, and osmium is then reoxidized by the chromate, which also cleaves the 1,2-diol. Under these conditions, olefin 11 afforded acid 17 in $80 \%$ isolated yield (Scheme-6).

Presence of a strong stretching band at $1709 \mathrm{~cm}^{-1}$, characteristic of a carboxylic acid carbonyl group in the IR spectrum of the product indicated the required transformation, which was further evident from the absence of two singlets, characteristic of isopropylidene methyl groups and a triplet of olefin proton in it's ${ }^{1} \mathrm{H}$ NMR spectrum. A carbonyl resonance at $\delta 180.3$ (s) in it's ${ }^{13} \mathrm{C}$ NMR spectrum further supported this.

Intermediate $\mathbf{1 7}$ was finally confirmed by it's mass spectrum, which revealed a peak of (M$1)^{+}$at 221 and was ascertained by it's elemental analysis also.

## Scheme-6

Reagents and conditions : a) $\mathrm{OsO}_{4}$ (cat), Jones' reagent, acetone, $r t, 5 h, 80 \%$; b) (i) $\mathrm{SOCl}_{2}$, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, reflux, 2 h; (ii) Meldrum's acid 19, pyridine, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to rt, 2 h ; (iii) MeOH, reflux, 4 h, $78 \%$; c) $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{MsN}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-5^{\circ} \mathrm{C}$ to rt, overnight.

To synthesize $\beta$-keto ester 18 from acid 17, Meldrum's acid, i. e. 2,2-dimethyl-1,3-dioxane-4,6-dione $\mathbf{1 9}^{10}$ was utilized. It could be easily acylated because of it's great acidity ( $p K a$ 13.7) to generate acyl Meldrum's acid, which on methanolysis afford corresponding $\beta$-ketoester. Thus, acid chloride, prepared from acid $\mathbf{1 7}$ using thionyl chloride, on treatment with Meldrum's acid 19 in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in presence of pyridine as the base, followed by methanolysis of the crude acyl Meldrum intermediate, afforded $\beta$-ketoester $\mathbf{1 8}$ as the sole product in $78 \%$ overall yield.

19 Meldrum's acid

Presence of two carbonyl stretching frequencies in the IR spectrum of the isolated product at $1747 \mathrm{~cm}^{-1}$, characteristic of an ester carbonyl and $1718 \mathrm{~cm}^{-1}$, characteristic of a keto carbonyl, indicated the formation of 1,3-diketone product, which was further supported by an additional three proton singlet at $\delta 3.69$ and a two proton singlet at $\delta 3.33$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum, assigned to $-\mathrm{COOC} \underline{H}_{3}$ and $-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{COOMe}$, respectively. This was further confirmed by two carbonyl resonances at $\delta 202.2$ and 167.2, and an additional methylene resonance at $\delta 48.7$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Finally, formation of intermediate $\mathbf{1 8}$ was confirmed by it's mass spectrum, which exhibited a peak at 279 $(\mathrm{M}+1)^{+}$and by it's elemental analysis also, found to be in good agreement with the calculated values.

After successfully synthesizing the key $\beta$-keto ester intermediate 18, the next job was to prepare $\alpha$-dizo- $\beta$-ketoester $\mathbf{1 0}$ and to check the feasibility of Taber's protocol for the formation of cyclopentanone with quaternary benzylic center.

Intermediate 10 was prepared by adopting Regitz's protocol of diazo transfer, ${ }^{11}$ according to which, $\beta$-ketoester $\mathbf{1 8}$ was treated with mesyl azide in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in presence of triethylamine as the base, which provided the required diazo product $\mathbf{1 0}$ (Scheme-6). The formation of $\mathbf{1 0}$ was confirmed by it's IR spectrum (revealed a characteristic absorption at $2136 \mathrm{~cm}^{-1}$ ), and was immediately subjected to diazodecomposition by treating it with catalytic amount of $\mathrm{Rh}_{2}(\mathrm{OAc})_{4}$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature, to afford cyclic $\beta$-ketoester 9 by C-H insertion at benzylic tertiary carbon atom, as a mixture of diastereomers in $35 \%$ overall yield from 18 (Scheme-7).

## Scheme-7

Reagents and conditions : a) $\mathrm{Rh}_{2}(\mathrm{OAc})_{4}$ (cat), $\mathrm{CH}_{2} \mathrm{Cl}_{2}, r t, 30 \mathrm{~min}, 35 \%$ overall from 18; b) $\mathrm{K}_{2} \mathrm{CO}_{3}$, MeI, acetone, rt, 24 h, 85\%.

Intermediate 9 was characterized by it's IR, NMR spectral analysis and finally confirmed by it's HRMS, which exhibited a peak of $\mathrm{M}^{+}$at 276.1363 (expected; 276.1361). Also, as reported, ${ }^{5}$ product should have retained the configuration at the reacting chiral center, which was decided to confirm by the sign of specific rotation of the final product, $i$. $e . \beta$-herbertenol, after completion of the synthesis and not at this stage.

The unstable cyclic $\beta$-ketoester 9 was further subjected to methylation using MeI in dry acetone using potassium carbonate as the base, which afforded single diastereomer $\mathbf{2 0}$ in $85 \%$ yield as the sole product with $100 \%$ diastereoselection, in which methyl and aryl groups on the adjacent quaternary carbons were anti to each other. The relative stereochemistry was proposed from it's ${ }^{1} \mathrm{H}$ NMR spectrum, in which the ester methyl singlet appeared at $\delta 3.30 \mathrm{ppm}$ because of the shielding of methoxy carbonyl group by the
vicinal cis aryl group. Further, quaternary singlets at $\delta 49.2$ and 64.4 supported the formation of this intermediate 20. Other characteristic signals in it's ${ }^{1} \mathrm{H}$ NMR spectrum were : two singlets at $\delta 1.26$ and 1.37 , each integrating for three protons, due to two adjacent cis-methyl groups; and a three proton singlet at $\delta 2.19$, assigned to $\mathrm{Ar}-\mathrm{CH}_{3}$. It's mass spectrum revealed a peak of $(\mathrm{M}+1)^{+}$at 291 , thus confirmed the product formation, which was further ascertained by it's elemental analysis as well.

Having secured the requisite cyclopentanone 20, deoxygenation of the two carbonyl functionalities followed by methyl ether deprotection should complete the synthesis of the target molecule, and this was achieved via diol intermediate 21, which was synthesized by lithium aluminium hydride reduction of the ketoester $\mathbf{2 0}$ in dry THF at room temperature, in $80 \%$ isolated yield (Scheme-8).

## Scheme-8

Reagents and conditions : a) $\mathrm{LAH}, \mathrm{THF}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 5 \mathrm{~h}, 80 \%$; b) pivaloyl chloride, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, $-10^{\circ} \mathrm{C}$ to rt, $4 \mathrm{~h}, 65 \%$.

Intermediate 21 was a white crystalline solid having mp 133-134 ${ }^{\circ} \mathrm{C}$. Presence of two absorption frequencies at $3625 \mathrm{~cm}^{-1}$ and $3350 \mathrm{~cm}^{-1}$, characteristic of primary and secondary hydroxyl groups; and absence of a carbonyl absorption in it's IR spectrum suggested the formation of the proposed diol 21. This was further evident from it's ${ }^{13} \mathrm{C}$ NMR spectrum, which revealed a methine resonance at $\delta 82.9$, assigned to $\underline{\mathrm{C}} \mathrm{H}-\mathrm{OH}$ and a methylene triplet at $\delta 67.6$, assigned to $\mathrm{CH}_{2}-\mathrm{OH}$. Other characteristic signals in it's ${ }^{1} \mathrm{H}$ NMR spectrum were : two doublets at $\delta 3.56$ and 3.76 , each integrating for one proton with same coupling constant value ( $J=11.2 \mathrm{~Hz}$ ), were assigned to $\mathrm{CH}_{2} \mathrm{OH}$; and a doublet of doublet of one proton at $\delta 4.21(J=8.8,6.4 \mathrm{~Hz})$ was assigned to $\mathrm{CH}-\mathrm{OH}$. Finally, diol 21 was confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+1)^{+}$at 265 and by it's elemental analysis also.

## Figure-1 : ORTEP view of rac-21

The relative stereochemistry in diol $\mathbf{2 1}$ was proposed on the basis of a single crystal X-ray analysis of the corresponding racemic product. The ORTEP view of rac-21 is reproduced in the figure-1, which further confirmed the relative stereochemistry at adjacent quaternary centers, i.e. at C2B and C3B as proposed earlier for intermediate 20.

Keeping in mind the efficiency of Barton-McCombie's protocol ${ }^{12}$ for deoxygenation of secondary alcohols, a stepwise deoxygenation was planned, i. e. first deoxygenation of secondary hydroxyl group and this warranted selective protection of the primary hydroxyl group, for which bulky pivaloyl ester derivative was opted. Thus, diol 21 on treatment with pivaloyl chloride in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in presence of $\mathrm{Et}_{3} \mathrm{~N}$ as the base at $0{ }^{\circ} \mathrm{C}$ provided the required monopivaloyl ester $\mathbf{2 2}$ in $65 \%$ isolated yield (Scheme-8).

Formation of the monoester derivative 22 was evident from the only carbonyl stretching frequency at $1718 \mathrm{~cm}^{-1}$ in it's IR spectrum, which further revealed only one hydroxyl absorption at $3407 \mathrm{~cm}^{-1}$. Also, downfield shift of two doublets of $-\mathrm{CH}_{2} \mathrm{OR}$ at $\delta$ 3.73 and $3.76(J=11.5 \mathrm{~Hz})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum was suggestive of an ester formation at the primary hydroxyl group, while a doublet of doublet associated with - CHOH was not shifted downfield, which indicated the selectivity in ester formation. A singlet at $\delta$ 1.17,
which integrated for nine protons, assigned to the three methyl groups of the pivaloyl ester, supported the presence of monoester. This was further confirmed by it's ${ }^{13} \mathrm{C}$ NMR spectrum, which revealed only one carbonyl resonance at $\delta 178.3$. Finally, mass spectrum confirmed the formation of $\mathbf{2 2}$ by exhibiting a peak at $349(\mathrm{M}+1)^{+}$, which was also ascertained by elemental analysis.

As Barton-McCombie's deoxygenation protocol involves treatment of the corresponding xanthate esters with tri- $n$-butyltin hydride, it was required to synthesize xanthate derivative 23, which was achieved in $95 \%$ yield by treating alkoxide ion, generated from alcohol 22 using NaH as the base, with carbon disulfide followed by MeI in dry THF (Scheme-9).

## Scheme-9

$22 \mathrm{R}=\mathrm{C}(\mathrm{O}) \mathrm{CMe}_{3}$

$23 \mathrm{R}=\mathrm{C}(\mathrm{O}) \mathrm{CMe}_{3}$

$24 \mathrm{R}=\mathrm{C}(\mathrm{O}) \mathrm{CMe}_{3}$

Reagents and conditions : a) NaH, CS 2, THF, $0^{\circ} \mathrm{C}, 2 \mathrm{~h}, \mathrm{MeI}, \mathrm{rt}, 5 \mathrm{~h}, 95 \%$; b) TBTH, AIBN (cat), toluene, reflux, 3 h, $80 \%$.

Absence of hydroxyl group stretching frequency in the IR spectrum and downfield shift of the proton, attached to the carbon bearing secondary hydroxyl group, from $\delta 4.08$ to $5.75(\mathrm{dd}, J=8.8,4.8 \mathrm{~Hz})$ in the ${ }^{1} \mathrm{H}$ NMR spectrum of the isolated product, suggested the formation of requisite $S$-methyldithiocarbonate 23, which was further confirmed by the presence of a resonance at $\delta 214.8$, attributed to the thiocarbonyl group, in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Intermediate $\mathbf{2 3}$ was, finally confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+2)^{+}$at 440 and ascertained by it's elemental analysis also.

Xanthate derivative 23 was then subjected to Barton's conditions, according to which it was treated with TBTH in refluxing toluene in the presence of catalytic amount of AIBN (radical initiator) to afford the requisite deoxygenated ester $\mathbf{2 4}$ in $80 \%$ isolated yield (Scheme-9).

Absence of one proton resonance at $\delta 5.75$ (dd) and presence of five proton multiplet ranged over $\delta 1.48-1.84$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum indicated the required transformation, which was further supported by absence of a thiocarbonyl resonance at $\delta$ 214.8 and presence of an additional methylene triplet at $\delta 20.1$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Formation of intermediate $\mathbf{2 4}$ was finally established by it's mass spectral data and elemental analysis.

The remaining task to be performed was deoxygenation of primary hydroxyl group, which could be achieved by Wolff-Kishner reduction of the corresponding aldehyde and for this purpose, pivaloyl protecting group was first removed using LAH in quantitative yield to result in alcohol 25 (Scheme-10). Intermediate $\mathbf{2 5}$ was easily characterized by the presence of an absorption at $3378 \mathrm{~cm}^{-1}$ in it's IR spectrum, characteristic of an hydroxyl functionality. It was further characterized by it's NMR spectral analysis and finally confirmed by it's mass spectrum and elemental analysis also. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2 5}$ revealed following characteristic resonances : two singlets at $\delta 1.12$ and 1.29 , each integrated for three protons, assigned to the vicinal methyl groups; a singlet at $\delta 2.23(3 \mathrm{H})$, assigned to the methyl group attached to the aromatic ring; two doublets at $\delta 3.03$ and 3.11 $(J=11.1 \mathrm{~Hz})$, integrated for one proton each, owed to $-\mathrm{CH}_{2} \mathrm{OH}$; a singlet at $\delta 3.81(3 \mathrm{H})$ was assigned to $\operatorname{Ar-OC} \underline{H}_{3}$; a doublet at $\delta 6.74(J=8.4 \mathrm{~Hz}, 1 \mathrm{H})$ and a multiplet ranged over $\delta$ 7.15-7.20 $(2 \mathrm{H})$, were due to protons associated with the aromatic ring.

## Scheme-10

Reagents and conditions : a) LAH, THF, rt, 2 h , quantitative; b) $\mathrm{PDC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}, 3 \mathrm{~h}$; c) $\mathrm{N}_{2} \mathrm{H}_{4^{-}}$ $\mathrm{H}_{2} \mathrm{O}$, diethyleneglycol, $\mathrm{NaOH}, 150^{\circ} \mathrm{C}, 4 \mathrm{~h}, 190^{\circ} \mathrm{C}, 3 \mathrm{~h}, 73 \%$ from 25; d) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}$ to rt , overnight, 93\%.

Oxidation of alcohol 25 using pyridinium dichromate, provided the aldehyde intermediate 26, which was characterized by it's ${ }^{1} \mathrm{H}$ NMR spectrum only (revealed a singlet at $\delta 9.0$, characteristic of an aldehyde proton), and was immediately subjected to deoxygenation, owing to it's unstability, using Huang-Minlon modification ${ }^{13}$ of WolfKishner reduction protocol. Accordingly, it was treated with hydrazine hydrate in diethylene glycol in presence of potassium hydroxide at $190{ }^{\circ} \mathrm{C}$, which resulted in formation of $\beta$-herbertenol methyl ether 27 in $73 \%$ overall yield from 25 (Scheme-10).

An additional methyl singlet at $\delta 0.64$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum and a methyl resonance at $\delta 24.4$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum were indicative of formation of 27 , which was further characterized by comparison of it's IR and NMR spectral data with those of reported one ${ }^{14}$ and were found to be in good agreement.

Finally, to complete the synthesis of $\beta$-herbertenol 1, methyl ether of 27 was deprotected using boron tribromide in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, in $93 \%$ yield (Scheme-10). Formation of a phenol derivative was evident from the presence of an hydroxyl absorption at $3450 \mathrm{~cm}^{-}$ ${ }^{1}$ in it's IR spectrum and disappearance of a three proton singlet at $\delta 3.87$ from the ${ }^{1} \mathrm{H}$ NMR spectrum. The physical and chemical properties of 1, thus obtained, were in good agreement with the literature values, ${ }^{2}$ except sign of it's specific rotation, which was due to the opposite configuration. It showed specific rotation $[\propto]^{25}{ }_{\mathrm{D}}+61.26\left(c 0.7, \mathrm{CHCl}_{3}\right)\left\{\right.$ lit. $^{2}$ $\left.[\propto]^{25}{ }_{\mathrm{D}}-47.0\left(c 0.7, \mathrm{CHCl}_{3}\right)\right\}$, which also suggested the optical purity of the product.

### 1.2.3 Conclusions

Thus, (+)- $\beta$-herbertenol 1 has successfully been synthesized enantiospecifically using naturally occurring monoterpene $(R)-(+)$-citronellal as the source of chirality, using Taber's protocol of diazodecomposition as the key step. Similar strategy can be applicable to the synthesis of it's natural isomer, i. e. (-)- $\beta$-herbertenol and other biologically active phenolic herbertanes also.

### 1.2.4 Experimental

## 6-Bromo-6-methyl-4-((R)-6-methylhept-5-en-2- yl)cyclohex-2-enone (15)

A 1 lit round bottom flask equipped with a magnetic stir bar and a condenser was charged with diisopropylamine (18.01 g, 178 mmol ) and dry THF ( 250 mL ) under $\mathrm{N}_{2}$ atmosphere, and cooled to $-78{ }^{\circ} \mathrm{C} . \mathrm{n}-\mathrm{BuLi}(102 \mathrm{~mL}, 164 \mathrm{mmol})(1.6 \mathrm{M}$ solution in hexane) was added dropwise and stirred for 10 min , followed by dropwise addition of enone $12(30 \mathrm{~g}, 136 \mathrm{mmol})$ in dry THF ( 50 mL ). The reaction mixture was stirred for 1.5 h at $-78{ }^{\circ} \mathrm{C}$ and then quenched using chlorotrimethylsilane ( $16.30 \mathrm{~g}, 150 \mathrm{mmol}$ ). It was allowed to come to $0{ }^{\circ} \mathrm{C}$ within 5 h and quenched with saturated $\mathrm{NaHCO}_{3}$ solution ( 200 mL ), extracted with pet. ether ( 250 mL x $3)$ and the combined organic layers were washed with brine ( 300 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure to give 38 g of crude silyl enol ether 14 , which was confirmed by it's ${ }^{1} \mathrm{H}$ NMR spectrum.

To an ice-cold solution of crude silyl enol ether 14 ( 38 g ) in dry THF ( 300 mL ) was added $N$-bromosuccinimide ( $26.70 \mathrm{~g}, 150 \mathrm{mmol}$ ) portionwise, stirred for 30 min at $0{ }^{\circ} \mathrm{C}$ and quenched with saturated $\mathrm{NaHCO}_{3}$ solution ( 300 mL ). It was then extracted with pet. ether ( $300 \mathrm{~mL} \times 2$ ), and the combined organic layers were washed with brine ( 500 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure to give 37 g of crude $\propto$-bromo enone $\mathbf{1 5}$ (mixture of diastereomers), which was directly used for the dehydrohalogenation.

Molecular Formula $: \mathrm{C}_{15} \mathrm{H}_{23} \mathrm{BrO}$

## (R)-2-Methyl-4-(6-methylhept-5-en-2-yl)phenol (16)

To a solution of crude $\propto$-bromo enone 15 in dry DMF ( 300 mL ) under $\mathrm{N}_{2}$ atmosphere, was added lithium carbonate ( $30.23 \mathrm{~g}, 409$ mmol ) and lithium bromide ( $23.69 \mathrm{~g}, 273 \mathrm{mmol}$ ) and was stirred at $130-140^{\circ} \mathrm{C}$ for 4 h . The reaction mixture was allowed to come to room temperature and DMF was removed under reduced pressure. The residue was diluted with water $(300 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(300 \mathrm{~mL}$ $x$ 3). The combined organic layers were washed with water ( $600 \mathrm{~mL} x 2$ ) and brine ( 600 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, 96:4) to provide phenol $16(22.2 \mathrm{~g})$ as a colourless oil.

## (R)-Methyl-6-(4-methoxy-3-methylphenyl)-3-oxoheptanoate (18)

To a solution of acid $\mathbf{1 7}(14 \mathrm{~g}, 63 \mathrm{mmol})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 150 mL ) was added thionyl chloride $(9.0 \mathrm{~g}, 75.60 \mathrm{mmol}$ ) and catalytic amount of DMF ( 0.5 mL ), under $\mathrm{N}_{2}$ atmosphere. The reaction mixture was refluxed for 2 h and then $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was removed at atmospheric pressure.

To remove the traces of thionyl chloride, dry benzene ( 25 mL ) was added to the residue and distilled off under reduced pressure. The residue was used as such for the next step.

A 500 ml round-bottom flask equipped with a magnetic stir bar was charged with Meldrum's acid 19 ( $9.54 \mathrm{~g}, 66.30 \mathrm{mmol}$ ) and dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(150 \mathrm{~mL})$, under $\mathrm{N}_{2}$ atmosphere. The reaction mixture was cooled to $-5^{\circ} \mathrm{C}$ and pyridine ( $12.46 \mathrm{~g}, 158 \mathrm{mmol}$ ) was added to
it. After stirring for 30 min at $0{ }^{\circ} \mathrm{C}$, acid chloride in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{~mL})$ was added dropwise. The reaction mixture was stirred at $0{ }^{\circ} \mathrm{C}$ for 1 h and at room temperature for an additional hour, followed by dilution with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The reaction mixture was poured to 2 N HCl solution ( 175 mL ) containing crushed ice and aqueous layer was extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $150 \mathrm{~mL} \times 2$ ). The combined organic layers were washed with 2 N HCl solution ( 200 mL ), water ( 200 mL ) and finally with brine ( 200 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure to give crude acyl Meldrum derivative, which was taken in dry methanol ( 300 mL ) and refluxed for $4-5 \mathrm{~h}$. Methanol was removed under reduced pressure and the residue was chromatographed using flash silica gel (pet. ether : EtOAc, $92: 8)$ to give $\beta$-ketoester $\mathbf{1 8}(13.67 \mathrm{~g})$ as a yellow oil.

Diffraction analysis of $\boldsymbol{r a c}-\mathbf{2 1}\left(\mathrm{C}_{16} \mathrm{H}_{24} \mathrm{O}_{3}\right.$, MZ 264.35). Single crystal of compound 21 obtained from S. P. Chavan et al. / Tetrahedron 61 (2005) 3873-3879, ethyl acetatepetroleum ether mixture. X-ray intensity data were collected on a Bruker SMART APEX CCD diffractometer with graphite-monochromatized (Mo KaZ $0.71073 \mathrm{~A}^{\circ}$ ) radiation at room temperature. All the data were corrected for Lorentzian, polarization and absorption effects using Bruker's SAINT and SADABS programs. SHELX-97 (G. M. Sheldrick, SHELX-97 program for crystal structure solution and refinement, University of Gottingen, Germany, 1997) was used for structure solution and full matrix least squares refinement on F2. Hydrogen atoms were included in the refinement as per the riding model.

((1S,2S,5S)-5-Hydroxy-2-(4-methoxy-3-methylphenyl)-1,2dimethylcyclopentyl)methylpivalate (22)

To a solution of diol $21(0.59 \mathrm{~g}, 2.24 \mathrm{mmol})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{~mL})$ maintained under $\mathrm{N}_{2}$ atmosphere, was added triethylamine ( $0.27 \mathrm{~g}, 2.68 \mathrm{mmol}$ ), and it was cooled to $-10{ }^{\circ} \mathrm{C}$. Pivaloyl chloride $(0.28 \mathrm{~g}, 2.35 \mathrm{mmol})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ was added and it was stirred at $0{ }^{\circ} \mathrm{C}$ for 4 h , diluted with water ( 50 mL ). The aqueous layer was extracted using

$\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 25 mL x 3 ), the combined organic layers were washed with brine ( 50 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, 9 : 1) to provide pivaloyl ester $22(0.51 \mathrm{~g})$ as a colourless oil.

((1S,2S,5S)-2-(4-Methoxy-3-methylphenyl)-1,2-dimethyl-5(methylthiocarbonothioloxy)cyclopentyl)methylpivalate (23)

A 50 mL two-neck round-bottom flask was charged with $\mathrm{NaH}(60 \%)(0.12 \mathrm{~g}, 3.0 \mathrm{mmol})$ and dry THF ( 7 mL ). Alcohol $22(0.7 \mathrm{~g}, 2.0 \mathrm{mmol})$ in dry THF ( 7 mL ) was added at $0{ }^{\circ} \mathrm{C}$, under $\mathrm{N}_{2}$ atmosphere and stirred for 30 min . Then, carbon disulphide $(0.23 \mathrm{~g}, 3.0 \mathrm{mmol})$ was added at $0{ }^{\circ} \mathrm{C}$ and stirred for 2 h at room temperature, followed by addition of iodomethane $(0.85 \mathrm{~g}, 6.0 \mathrm{mmol})$ at $0{ }^{\circ} \mathrm{C}$. It was stirred for
additional 5 h at room temperature, diluted with ice water ( 30 mL ) and extracted with ethyl acetate ( $20 \mathrm{~mL} x \mathrm{3}$ ). The combined organic layers were washed with water ( 30 mL ), brine ( 30 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, $98: 2$ ) to give xanthate $\mathbf{2 3}(0.83 \mathrm{~g})$ as a colourless oil.

( $\boldsymbol{R}$ )-1-Methoxy-2-methyl-4-(1,2,2-trimethylcyclopentyl)benzene (27) ${ }^{14}$

To a stirred solution of alcohol $25(0.1 \mathrm{~g}, 0.4 \mathrm{mmol})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(10 \mathrm{~mL})$ was added pyridinium dichromate $(0.228 \mathrm{~g}, 0.6 \mathrm{mmol})$ portionwise at $0^{\circ} \mathrm{C}$ and allowed to stir at room temperature for 3 h . The reaction mixture was then diluted with diethyl ether ( 25 mL ) and filtered through a short pad of celite, which was washed with diethyl ether ( $25 \mathrm{~mL} \times 2$ ). The combined organic layers were then washed with water (30 mL ), brine ( 30 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue ( 0.11 g ) was directly used for the next step, as aldehyde 26 was unstable. To a stirred solution of crude aldehyde 26 in diethylene glycol ( 4 mL ) was added hydrazine monohydrate $(0.024 \mathrm{~g}, 0.48 \mathrm{mmol})$ and sodium hydroxide $(0.355 \mathrm{~g}, 8.875$ $\mathrm{mmol})$. The reaction mixture was stirred at $150{ }^{\circ} \mathrm{C}$ for 4 h and at $190{ }^{\circ} \mathrm{C}$ for additional 3 h . The reaction mixture was diluted with water ( 25 mL ) and extracted using diethyl ether (15 $\mathrm{mL} x$ 2). The combined organic layers were then washed with water ( 20 mL ), brine ( 20 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, 99 : 1) to give 27 $(68 \mathrm{mg})$ as a colourless oil.

Chapter-2 : Syntheses of(-)-Parvifoline, (+)-Isoparvifolinone and (-)-Curcuquinone Section-1 : Synthesis of Parvifoline $\mathcal{L}$ Curcuquinone: $\mathcal{A}$ Brief Review

### 2.1.1 Introduction

(-)-Parvifoline $\mathbf{1}$ is a bicyclic phenolic sesquiterpene, isolated from the genera Coreopsis ${ }^{1}$ and Perezia ${ }^{2}$ along with (+)-isoparvifolinone 2 and parvifoline isovalerate 1a. These are the only natural substances, which contain trimethyl benzocyclooctene skeleton. Structure of parvifoline 1 was deduced from it's spectral data and a few chemical transformations, but no conclusive evidence about it's absolute configuration was described. However, it was later proved to be $\boldsymbol{R}$ by it's chemical transformation ${ }^{3}$ into another sesquiterpene of known absolute configuration, called (-)-curcuquinone 4.

$1 \mathrm{R}=\mathrm{H}$
1a $\mathrm{R}=\mathrm{Me}_{2} \mathrm{CHCH}_{2} \mathrm{C}(\mathrm{O})$

3a $\mathrm{R}_{1}=\mathrm{H} ; \mathrm{R}_{2}=\mathrm{OH}$
3b $\mathrm{R}_{1}=\mathrm{OH} ; \mathrm{R}_{2}=\mathrm{OH}$

2

4
(-)-Curcuquinone $\mathbf{4}$ is the simplest monocyclic sesquiterpene benzoquinone, which was isolated from the Pseudoterogorgia rigida ${ }^{4}$ together with two aromatic bisabolene sesquiterpenoids, named (-)-curcuphenol 3a and (-)-curcuhydroquinone 3b. All these compounds show antibacterial activity, but more importantly they have proven to be versatile chiral building blocks for the synthesis of related important natural products, such as heliannuols, ${ }^{5}$ which represents a group of allelochemical phenolic sesquiterpenes.

### 2.1.2 Structure determination

(-)-Parvifoline $\mathbf{1}$ is a crystalline compound having mp $89-90{ }^{\circ} \mathrm{C}$ and specific rotation $[\alpha]^{25}{ }_{D}-173\left(c 1.73, \mathrm{CHCl}_{3}\right)$. It was analyzed for $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}$; and presence of oxygen as a phenolic group was proved from the IR spectra of the natural product and of the derived crystalline acetate, which showed absorptions at $3610 \mathrm{~cm}^{-1}$ and $1765 \mathrm{~cm}^{-1}$ respectively. However, it gave a negative $\mathrm{FeCl}_{3}$ test, but from it's ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra, it was confirmed to be a phenol derivative. The singlet at $\delta 152.5 \mathrm{ppm}$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum was indicative of the phenolic nature of the natural product. Also, the aromatic ring was evident from the three more singlets at $\delta 143.9,130.7,120.4$; and two doublets at $\delta 111.3$ and 131.8 in it's ${ }^{13} \mathrm{C}$ NMR spectrum. It's ${ }^{1} \mathrm{H}$ NMR spectrum also supported the presence of aromatic ring with two aromatic para distributed protons by revealing two singlets at $\delta 6.91$ and 6.62 . In ${ }^{13} \mathrm{C}$ NMR spectrum, signals at $\delta 123.3$ (d) and 137.5 (s) indicated the presence of a trisubstituted double bond, which was further supported by the resonance in ${ }^{1} \mathrm{H}$ NMR spectrum at $\delta 1.74$ (br s) for three protons, corresponds to an allylic methyl group and $\delta 5.36(\mathrm{t}, J=7.0 \mathrm{~Hz})$ for one proton attached to the trisubstituted olefin. The remaining $s p^{3}$ signals were due to a secondary methyl group at benzylic position, a quartet at $\delta 19.2$ and a doublet at $\delta 33.1$ in the ${ }^{13} \mathrm{C}$ NMR spectrum. The secondary methyl group was further evident from a three proton doublet at $\delta 1.30(J=7.0 \mathrm{~Hz})$, which was coupled to one proton methine multiplet at $\delta 3.18$, in it's ${ }^{1} \mathrm{H}$ NMR spectrum. From all these spectral data, structure $\mathbf{1}$ was proposed for ( - )-parvifoline.
(+)-Isoparvifolinone 2 is a solid compound (mp 157-158 ${ }^{\circ} \mathrm{C}$ ) having molecular formula $\mathrm{C}_{15} \mathrm{H}_{18} \mathrm{O}_{2}$. The nature of the two oxygen atoms was defined after inspection of it's IR spectrum, which revealed absorptions at $3600 \mathrm{~cm}^{-1}$ and $3350 \mathrm{~cm}^{-1}$, attributed to an hydroxyl group. Also, it showed bands at $1660 \mathrm{~cm}^{-1}$ and $1590 \mathrm{~cm}^{-1}$, corresponding to a conjugated carbonyl group, which was further confirmed from the UV absorption at 3.37 $\mathrm{nm}(\varepsilon 9200)$. The phenolic nature and substitution pattern in the aromatic ring were deduced after inspection of the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectral data. Apart from signals due to aromatic ring, other $s p^{2}{ }^{13} \mathrm{C}$ signals were ascribed to a carbonyl group at $\delta 205.4$, which is in conjugation with a trisubstituted double bond, responsible for a singlet at $\delta 135.6$ and a doublet at $\delta 140.2$. One of the substituents of the double bond was a methyl group, responsible for a three proton doublet at $\delta 2.02(J=1.7 \mathrm{~Hz})$, coupled to a vinyl proton that appeared as a quartet with further unresolved long range couplings at $\delta 7.11(J=1.7 \mathrm{~Hz})$. It's chemical shift being indicative of it's $\beta$-relation to the carbonyl group. All these data
and also bearing in mind those of parvifoline 1, structure 2 was proposed for (+)isoparvifolinone. Definitive evidence was obtained by it's partial synthesis from (-)parvifoline 1.
(-)-Curcuquinone 4 was isolated as a viscous yellow oil, which showed quinoid absorption at $1650 \mathrm{~cm}^{-1}$ in it's IR spectrum and $\lambda_{\text {max }} 253 \mathrm{~nm}(\varepsilon 10,200)$ in it's UV spectrum. High resolution mass spectrometry indicated the parent ion composition of $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{2}$. From comparison of it's NMR spectral data with those of curcuphenol 3a, structure 4 was proposed for (-)-curcuquinone. Here are significant and characteristic resonances present in it's ${ }^{1} \mathrm{H}$ NMR spectrum : the only secondary methyl group at $\delta 1.11$ (d, $J=7.0 \mathrm{~Hz}, 3 \mathrm{H})$; two olefin protons at $\delta 6.42(\mathrm{~s}, 1 \mathrm{H})$ and $6.52(\mathrm{q}, J=1.6 \mathrm{~Hz}, 1 \mathrm{H})$; one proton of isopropylidene group at $\delta 5.01(\mathrm{dd}, J=7.0,7.0 \mathrm{~Hz})$; two methyl groups of isopropylidene functionality at $\delta 1.50(\mathrm{~s})$ and $1.66(\mathrm{~s})$; remaining allylic methyl group (attached to the ring) at $\delta 1.98$, further coupled to the adjacent olefin proton $(J=1.6 \mathrm{~Hz})$.

### 2.1.3 Conformation and absolute configuration determination of Parvifoline : (Scheme-1, 1988)

As mentioned earlier, absolute configuration of (-)-parvifoline $\mathbf{1}$ was determined by it's conversion to (-)-curcuquinone 4, a sesquiterpene with established absolute configuration. This particular work was done by Joseph-Nathan et al ${ }^{3}$ after a decade of the isolation of (-)-parvifoline. Scheme-1 represents the reaction sequence using which (-)parvifoline was transformed to curcuquinone.

Accordingly, (-)-1 was protected as it's benzoate ester and subjected to acidic conditions to isomerise the double bond. It was achieved using $\mathrm{HOAc} / \mathrm{ZnCl}_{2}$ to yield isoparvifoline benzoate 5 , which was epoxidized using mCPBA followed by periodic acid cleavage to provide keto-aldehyde 7. It was then hydrolyzed under alkaline condition, followed by oxidative decarbonylation using hydrogen peroxide to give quinone 8 . It was then converted to the hydroquinone diester $\mathbf{9}$, which on 1,2 -addition over side chain carbonyl group using MeMgI and oxidation of the resulting hydroquinone, provided $\mathbf{1 0}$. Dehydration of tertiary hydroxyl group of $\mathbf{1 0}$ using silica gel $/ p$ TSA yielded curcuquinone 4, identical to the natural product in all respect.

Scheme-1 : (Joseph-Nathan et al, J. Nat. Prod. 1988, 51(4), 675-689)

Reagents and conditions : a) (i) benzoyl chloride, pyridine; (ii) $\mathrm{HOAc}, \mathrm{ZnCl}_{2}, 94 \%$; b) $m C P B A$, $65 \%$; c) $\mathrm{HIO}_{4}, 62 \%$; d) (i) $\mathrm{KOH}, \mathrm{MeOH}, 89 \%$; (ii) $\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{MeOH}, 48 \%$; e) $\mathrm{Zn}, \mathrm{Ac}_{2} \mathrm{O}$, $\mathrm{NaOAc}, 78 \%$; f) (i) MeMgI; (ii) aq. $\mathrm{FeCl}_{3}, \mathrm{MeOH}, 68 \%$; g) TsOH, silica gel, $48 \%$.

Curcuquinone 4 obtained from (-)-parvifoline 1 showed $[\alpha]^{25}{ }_{D}-1.58$, a value very close to that of reported for the natural product, ${ }^{4}$ that is $[\alpha]^{25}-1.3$. Now, as absolute configuration of (-)-curcuquinone is $\boldsymbol{R}$, it follows that (-)-parvifoline $\mathbf{1}$ also has the same absolute configuration, that is $\boldsymbol{R}$.

The conformations in solution were also deduced for derivatives $\mathbf{1 b}, 5$ and $\mathbf{6}$ using their ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectral data, two dimensional ${ }^{1} \mathrm{H} /{ }^{13} \mathrm{C}$ heteronuclear chemical shift correlation diagrams and by $\mathrm{H}-\mathrm{C}-\mathrm{C}-\mathrm{H}$ dihedral angles determinations. The X-ray diffraction analysis of compounds $\mathbf{1 b}, \mathbf{5}$ and $\mathbf{6}$ were also recorded and results regarding conformation in solid state then compared with those in solution, which showed that in each case the conformations were essentially same. From all these data, conformation of
the eight membered ring in $\mathbf{1}$ was proposed to be distorted twist boat, which also justifies the high specific rotation values of (-)-parvifoline $\mathbf{1}$ and (+)-isoparvifolinone 2 (probably due to the presence of inherently dissymmetric chromophores).

### 2.1.4 Total Synthesis of Parvifoline : A Brief Review

The main structural features that challenge the synthesis of parvifoline and isoparvifolinone are; (i) formation of benzocyclooctene framework and (ii) presence of a double bond next to conjugation, in case of parvifoline. There have been total four approaches reported todate for the synthesis of rac-parvifoline $\mathbf{1}$, three of them used Grob fragmentation strategy, while the other one dealt with Dieckmann type intramolecular cyclisation of an ester sulfone. Apart from these approaches; in 1987, Bohlmann et al attempted synthesis of parvifoline following biomimetic pathway, but instead ended up in the synthesis of 2-hydroxycalamenene 17. Further, in the year 1989, synthesis of isoparvifoline $\mathbf{3 0}$ was reported by Rao et al. These two attempts constitute the initial efforts towards synthesis of the title compounds.

## Bohlmann's Attempt : (Scheme-2 and 3, 1987) ${ }^{6}$

This was the first attempt towards the synthesis of rac-parvifoline 1, however, it was a failure, but the authors were successful in synthesizing three other sesquiterpenes named; xanthorrhizol 14, hydroxy calamenene 17 and hydroxy cadalene 21.

## Scheme-2

The idea behind the synthesis was to check the feasibility of the proposed biomimetic pathway (Scheme-2) for the chemical synthesis of parvifoline from an unnatural 13-hydroxy xanthorrhizol 11.

Scheme-3 : (Bohlmann et al, Tetrahedron Lett. 1987, 28, 2575-2578)

21

Reagents and conditions : a) (i) $\mathrm{Me}_{2} \mathrm{C}=\mathrm{CHCH}_{2} \mathrm{CH}_{2} \mathrm{MgBr}, \mathrm{NH}_{4} \mathrm{Cl}$; (ii) $\mathrm{Et}_{3} \mathrm{SiH}, \mathrm{BF}_{3}-\mathrm{OEt}_{2}, 70 \%$ overall; b) MeMgI, xylene, $85 \%$; c) (i) $\mathrm{ClCH}(\mathrm{Me}) \mathrm{OEt}, \mathrm{EtN}\left(\mathrm{CHMe}_{2}\right)_{2}$; (ii) $\mathrm{O}_{3}, \mathrm{Me}_{2} \mathrm{~S},-70^{\circ} \mathrm{C}$; (iii) $\mathrm{Ph}_{3} \mathrm{P}=$ CHMe, $-78{ }^{\circ} \mathrm{C}$; (iv) BuLi; (v) $\mathrm{CH}_{2} \mathrm{O}$; d) NCS, $\mathrm{Me}_{2} \mathrm{~S}, 0^{\circ} \mathrm{C}$; e) $\mathrm{KOBu} u^{t}$, tert-BuOH; f) $\mathrm{H}_{2} / \mathrm{Pd}$, $75 \%$; g) $\mathrm{O}_{3}, \mathrm{Me}_{2} \mathrm{~S},-70^{\circ} \mathrm{C}, 70 \%$; h) (i) $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{CHMe},-78^{\circ} \mathrm{C}$; (ii) BuLi; (iii) $\mathrm{CH}_{2} \mathrm{O}, 44 \%$ overall; i) (i) NCS, $\mathrm{Me}_{2} \mathrm{~S}, \mathrm{O}^{\circ} \mathrm{C}$; (ii) $\mathrm{ZnCl}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 24 \mathrm{~h}$; j) $\mathrm{BBr}_{3},-78^{\circ} \mathrm{C}$, $56 \%$ overall.

Accordingly, the key intermediate $\mathbf{1 5}$ was prepared from acetophenone $\mathbf{1 2}$ as depicted in the scheme-3, via xanthorrhizol 14 and allyl alcohol 11, which was subjected to the base treatment to afford 2-hydroxy calamenene $\mathbf{1 7}$ and not the required rac-1. Also,
anisole derivative $\mathbf{1 9}$ on chlorination followed by treatment of the resulting halide with zinc chloride in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, provided 2-methoxy cadalene 20.

## Rao's Attempt : (Scheme-4, 1989) ${ }^{7}$

In this particular attempt, authors have used cyclodehydration of acid $\mathbf{2 6}$ as the key step for benzocyclooctanone ring formation. However, they could not synthesize parvifoline and instead ended up in it's double bond isomer, i. e. isoparvifoline $\mathbf{3 0}$.

Scheme-4 : (Rao et al, Indian J. Chem. 1989, 28B, 219-222)

Reagents and conditions : a) $\mathrm{MeOH}, \mathrm{H}^{+}$; b) (i) MeMgI; (ii) NaOH , EtOH, reflux, 90\%; c) $\mathrm{Li}^{2} \mathrm{NH}_{3}$, $85 \%$; d) (i) $\mathrm{HNO}_{3}, \mathrm{H}_{2} \mathrm{SO}_{4}, 0^{\circ} \mathrm{C}$; (ii) $\mathrm{NaNO}_{2}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{MeOH},-10{ }^{\circ} \mathrm{C}$; (iii) $\mathrm{Me}_{2} \mathrm{SO}_{4}, \mathrm{NaOH}, 62 \%$ overall; e) PPA, $64 \%$; f) (i) $\mathrm{NaBH}_{4}, \mathrm{MeOH}$; (ii) DMF, $\mathrm{POCl}_{3}, 90{ }^{\circ} \mathrm{C}, \mathrm{NaOAc}, 73 \%$; g) $\mathrm{N}_{2} \mathrm{H}_{4}-\mathrm{H}_{2} \mathrm{O}$, DEG, KOH , reflux, 2 h, 65\%; h) $\mathrm{BBr}_{3}, 74 \%$.

Accordingly, acid 26 was prepared from keto acid 22, which on treatment with polyphosphoric acid underwent intramolecular cyclodehydration to furnish 27. It was further reduced using sodium borohydride, and was converted to the conjugated aldehyde 28 using Vilsmeier reaction, followed by deoxygenation of aldehyde to methyl group and deprotection of methyl ether $\mathbf{2 9}$ to provide isoparvifoline $\mathbf{3 0}$ (Scheme-4).

## Grimm's Approach : (Scheme-5, 1994) ${ }^{8}$

The synthesis reported by Grimm et al differs from the rest of the syntheses in benzocyclooctane framework formation, which was achieved by intramolecular ketosulfone cyclisation ${ }^{9}$ of $\mathbf{3 4}$.

Scheme-5 : (Grimm et al, Tetrahedron Lett. 1994, 35, 5369-5372)

Reagents and conditions : a) (i) MeN(Li) $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NHMe}$; (ii) $n$-BuLi; (iii) $\mathrm{I}_{2}$, $53 \%$ overall; b) (i) $\mathrm{LiCH}_{2} \mathrm{SO}_{2} \mathrm{Ph}$; (ii) $\mathrm{Et}_{3} \mathrm{SiH}$, TFA, $80 \%$ overall; c) (i) trans-3-penten-1-ol, $\mathrm{Pd}(\mathrm{OAc})_{2}$; (ii) $\mathrm{H}_{2} \mathrm{CrO}_{4}$; (iii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, 44 \%$ overall; d) LiHMDS, $80 \%$; e) (i) $\mathrm{NaBH}_{4}, \mathrm{MeOH}$; (ii) $\mathrm{CH}_{3} \mathrm{SO}_{2} \mathrm{Cl}, \mathrm{Et}_{3} \mathrm{~N}$; (iii) LiHMDS, $75 \%$ overall; f) $\mathrm{MeMgCl}, \mathrm{Ni}(\mathrm{acac})_{2}, 75 \%$; (ii) EtSNa, DMF, $150^{\circ} \mathrm{C}, 95 \%$.

Accordingly, the key intermediate sulfone ester 34 was synthesized from commercially available 3-methyl-4-anisaldehyde 31 (Scheme-5). Aldehyde 31 on $\alpha$-amino alkoxide directed lithiation followed by reaction with iodine provided the iodo aldehyde $\mathbf{3 2}$ in $53 \%$ isolated yield, which on treatment with the anion of methyl phenyl sulfone followed by reduction of the crude product with triethylsilane and trifluoroacetic acid, afforded iodosulfone $\mathbf{3 3}$ in $80 \%$ overall yield. Ester side chain introduction was achieved by using Larock's palladium catalyzed coupling protocol, which gave $\mathbf{3 4}$ after chromic acid oxidation of the resulting alcohol followed by esterification, in $44 \%$ overall yield. The crucial ring closure over $\mathbf{3 4}$ was performed using LiHMDS to give ketosulfone $\mathbf{3 5}$ in $80 \%$ yield as a mixture of diastereomers (9:1); followed by keto reduction, mesylation and it's
immediate elimination to give vinyl sulfone 36 in $75 \%$ overall yield. Methyl group was introduced using MgMgCl in the presence of $\mathrm{Ni}(\mathrm{acac})_{2}$ in $75 \%$ yield, followed by demethylation using sodium thioethoxide to give rac-parvifoline 1 in about $6 \%$ overall yield.

## Joseph-Nathan's Approach : (Scheme-6, 1995) ${ }^{10}$

The synthesis of rac-parvifoline reported by Joseph-Nathan et al $(1994,1995)$ was the first one to use Grob fragmentation reaction ${ }^{11}$ for cyclooctene ring formation. They used dibromo compound $\mathbf{3 7}$ as a starting material for the synthesis, which on treatment with 2-methyl-1,3-cyclopentanedione in presence of potassium carbonate as the base and butanol-water mixture as a solvent gave $C$-alkylated product $\mathbf{3 8}$ as the major one, together with $O$-alkylated product. One of the keto group of intermediate $\mathbf{3 8}$ was protected as a cyclic acetal, followed by mesyl group deprotection using potassium hydroxide in methanol to give corresponding phenol, which was further protected as it's methyl ether 39 and was treated with lithium in THF to afford tricyclic intermediate $\mathbf{4 0}$ in $43 \%$ yield from 39. Cyclic acetal of $\mathbf{4 0}$ was then deprotected under acidic condition followed by reduction of the keto group using sodium borohydride to give alcohol, which on mesylation gave the key intermediate $\mathbf{4 1}$ as the sole product. It possessed the required relative stereochemistry at $\mathrm{C}_{7}$ and $\mathrm{C}_{10}$ to stereospecifically produce the $Z$-isomer in a Grob fragmentation reaction. Indeed, when 41 was treated with sodium methoxide in methanol, benzocyclooctenone 42 was obtained in $80 \%$ yield.

Intermediate $\mathbf{4 2}$ was then treated with MeLi followed by deoxygenation of resulting benzylic hydroxyl group using triethylsilane and borontrifluoride, which instead resulted in double bond reduction product. Therefore, it was thought to protect the $\mathrm{C}_{6}-\mathrm{C}_{7}$ double bond as an epoxide. But, before epoxidation, alcohol 43 was treated with mesyl chloride in pyridine to have it's mesylate, but instead eliminated product, i. e. diene $\mathbf{4 4}$ was obtained in $80 \%$ yield. It was selectively epoxidized using mCPBA in $77 \%$ yield, followed by hydrogenation of the exocyclic double bond to give isomer 46. It was then treated with $p$ TSA in benzene to provide intermediate 47 in $70 \%$ yield, which was converted to racisoparvifolinone by $\mathrm{CrO}_{3}$ oxidation followed by demethylation using $\mathrm{BBr}_{3}$ in $43 \%$ overall yield. Further, 47 was hydrogenated to give alcohol $\mathbf{4 8}$, which was subjected to tosylation. Under this condition, it underwent elimination to give parvifoline methyl ether 49 in $83 \%$ yield, which was deprotected using lithium thioethoxide to give rac-1 in $98 \%$ yield.

Scheme-6 : (Joseph-Nathan et al, Tetrahedron 1995, 51, 9285-9300)

Reagents and conditions : a) 2-methyl-1,3-cyclopentanedione, $\mathrm{K}_{2} \mathrm{CO}_{3}, t-\mathrm{BuOH}: \mathrm{H}_{2} \mathrm{O}$ (1.2: 1), reflux, $3 \mathrm{~h}, 50 \%$; b) (i) ethylene glycol, pTSA, benzene, reflux, $95 \%$; (ii) КОН, МeOH, reflux, $74 \%$; (iii) dimethyl sulfate, acetone, reflux, $94 \%$; c) Li, THF, $20^{\circ} \mathrm{C}, 1 \mathrm{~h}, 43 \%$; d) (i) $\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{MeOH}, 20$ ${ }^{\circ} \mathrm{C}$, 30 min, $94 \%$; (ii) $\mathrm{NaBH}_{4}, \mathrm{MeOH}, 20^{\circ} \mathrm{C}$, $98 \%$; (iii) mesyl chloride, pyridine, $-4^{\circ} \mathrm{C}, 68 \%$; e) MeONa, MeOH, reflux, $2 \mathrm{~h}, 80 \%$; f) MeLi, THF, -78 to $-70^{\circ} \mathrm{C}, 3 \mathrm{~h}, 75 \%$; g) mesyl chloride, pyridine, $-4^{\circ} \mathrm{C}$, overnight, $80 \%$; h) mCPBA, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 40 \mathrm{~min}, 70 \%$; i) $\mathrm{Pd} / \mathrm{C} / \mathrm{H}_{2}, \mathrm{EtOH}, \mathrm{rt}, 95 \%$; j) pTSA, benzene, rt, 1 h, $70 \%$; k) (i) $\mathrm{CrO}_{3}$, pyridine, rt, $80 \%$; (ii) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 54 \%$; l) $\mathrm{Pd} / \mathrm{C}_{2} \mathrm{H}_{2}$, EtOH, rt, $1 \mathrm{~h}, 97 \%$; m) p-TsCl, pyridine, $-4^{\circ} \mathrm{C}, 36 \mathrm{~h}, 83 \%$; n) EtSLi, DMF, $85^{\circ} \mathrm{C}, 24 \mathrm{~h}, 98 \%$.

## Maldonado's Approach : (Scheme-7 and 8, 1998) ${ }^{12}$

This particular synthesis was also based on Grob fragmentation strategy, but the key intermediate was prepared by Stork-Landesman two carbon ring expansion ${ }^{13}$ of $\beta$ tetralone 51. They used readily available symmetrical naphthalene $\mathbf{5 0}$ as their starting material, which itself contains $80 \%$ of the carbon atoms of the target skeleton.

Scheme-7 : (Maldonado et al, J. Org. Chem. 1998, 63, 2918-2921)

Reagents and conditions : a) (i) Na, EtOH; (ii) $\mathrm{H}_{3} \mathrm{O}^{+}$, 95\% overall; b) pyrrolidine, benzene; c) acrolein, dioxane; d) (i) MeI, $\mathrm{CHCl}_{3}$; (ii) NaOH .

Accordingly, $\beta$-tetralone 51 was obtained from naphthalene $\mathbf{5 0}$ by $\mathrm{Na} / \mathrm{EtOH}$ reduction followed by acid catalyzed hydrolysis of the intermediate enol ether, in 95\% yield. The Stork-Landesman ring expansion sequence was then performed over tetralone 51. Thus, $\mathbf{5 1}$ was treated with pyrrolidine to give enamine $\mathbf{5 2}$, followed by it's reaction with acrolein to furnish bridged amino ketone 53. It was then quaternised using iodomethane and then treated with $15 \%$ aqueous NaOH solution to carry out Grob fragmentation. But instead of the required cyclooctene intermediate 56a, it ended up in impure 53, which was resulted by $N$-demethylation of the intermediate quaternary salt (Scheme-7).

This problem was then solved by mild acid treatment of $\mathbf{5 3}$ to give a mixture of ketols, which were separated by column chromatography and characterized by spectroscopy (and in the case of 55a by a single crystal X-ray analysis) as the equitorial and axial isomers (54a and 55a) in 3: 2 ratio and in 57\% overall yield (Scheme-8).

## Scheme-8

Reagents and conditions : a) $\mathrm{H}_{3} \mathrm{O}^{+}$, $57 \%$ overall; b) $\mathrm{MeSO}_{2} \mathrm{Cl}, \mathrm{Et}_{3} \mathrm{~N}$; c) NaOH , reflux, $2.5 \mathrm{~h}, 82 \%$; d) $\mathrm{CH}_{2} \mathrm{~N}_{2}$; e) $\mathrm{ClCOOEt}, \mathrm{THF}, \mathrm{Et}_{3} \mathrm{~N}$; f) $\mathrm{NaBH}_{4}, 78-87 \%$; g) (i) $\mathrm{MeSO}_{2} \mathrm{Cl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$; (ii) LiBHEt $_{3}$, THF, rt, 10 h, 55\%; (iii) EtSLi, DMF, $105^{\circ} \mathrm{C}, 48 \mathrm{~h}, 97 \%$.

Grob fragmentation was performed over mesyl ester 54b and 55b by refluxing them with $15 \%$ aqueous NaOH solution to give benzocyclooctene carboxylic acid 56a in $82 \%$ and $41 \%$ yield respectively. Finally, acid 56a was reduced and deoxygenated followed by deprotection of methyl ether to give the final product in fairly good overall yields. It was also claimed that, however synthesis involves 12 chemical steps, it could be executed in only five synthetic operations.

## Venkateswaran's Approach : (Scheme-9, 1999) ${ }^{14}$

In this formal synthesis, Mn (III)-catalyzed oxidative arylation ${ }^{15}$ of ketone $\mathbf{5 9}$ was used as the key step, according to which ketone 59 was treated with $\mathrm{Mn}(\mathrm{OAc})_{3}$ and $\mathrm{Cu}(\mathrm{OAc})_{2}-\mathrm{H}_{2} \mathrm{O}$ in acetic acid to provide the bridged bicyclo [3.3.1] nonadione $\mathbf{6 0}$ in $60 \%$ yield.

Scheme-9 : (Venkateswaran et al, Tetrahedron Lett. 1999, 40, 7431-7433)

Reagents and conditions : a) 2-methyl-1,3-cyclohexanedione, $\mathrm{NaOH}, \mathrm{H}_{2} \mathrm{O}, \mathrm{NaI}, 6{ }^{\circ} \mathrm{C}, 65 \%$; b) $\mathrm{Mn}(\mathrm{OAc})_{3}, \mathrm{Cu}(\mathrm{OAc})_{2}, \mathrm{HOAc}, 80^{\circ} \mathrm{C}, 60 \%$; c) $\mathrm{Li}(t-\mathrm{BuO})_{3} \mathrm{AlH}$, THF, reflux, $65 \%$.

The least hindered carbonyl group of $\mathbf{6 0}$ was then regio and stereoselectively reduced using lithium hydrido tri-tert-butoxyaluminate to produce the equitorial ketol 55a in $65 \%$ yield. This has previously been used for the synthesis of rac-1 by Maldonado et al ${ }^{12}$ using Grob fragmentation strategy.

### 2.1.5 Total Synthesis of Curcuquinone : A Brief review

The main structural feature that challenges the synthesis of (-)-curcuquinone $\mathbf{4}$ is the introduction of chirality at the nonfunctionalised allylic position, which reflects in the number of synthesis of enantiopure 4. There are four reports on the synthesis of optically pure curcuquinone, while the other three reported the synthesis of rac-4.

## Joseph-Nathan's Approach : (Scheme-10, 1981) ${ }^{16}$

This was the first synthesis of rac-4 and the corresponding hydroquinone 3b. Here, the key reaction was Grignard addition of arylmagnesium bromide, generated from 61, with commercially available 6-methyl-5-hepten-2-one, which gave benzyl alcohol 62. This intermediate was further converted to the target molecules following a few functional group transformations (Scheme-10).

Scheme-10 : (Joseph-Nathan et al, J. Org. Chem. 1981, 46, 4666-4667)

Reagents and conditions : a) Mg, 6-methyl-5-hepten-2-one, THF, reflux, 88\%; b) (i) amberlyst-15 (cat), benzene, rt; (ii) $\mathrm{Na}, \mathrm{NH}_{3},-78^{\circ} \mathrm{C}, 85 \%$ overall; c) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 90 \%$; d) air oxidation; e) $\mathrm{Ag}_{2} \mathrm{O}$, dioxane, $\mathrm{HNO}_{3}, \mathrm{rt}, 70 \%$.

## Ono's Approach : (Scheme-11, 1994) ${ }^{17}$

The idea behind this synthesis of rac-4 was to develop a route, which could be applicable to the synthesis of enantiopure curcuquinone 4 and that's why the key intermediate $\mathbf{6 8}$ in this strategy, had a hydroxyl methyl group at benzylic position of the bisabolene congener, which could be resolved.

64, aromatic bisabolene skeleton

65, Curcudiol

The reaction of $\alpha, \beta$-epoxyesters and nucleophiles such as alcohols or phenols in the presence of Lewis acid are reported to give $\alpha, \beta$-disubstituted esters, ${ }^{18}$ and this was used in
this particular approach for the synthesis of key intermediate 68. Accordingly, reaction of rac-66 and 67 gave rac-68 in $68 \%$ yield, together with $11 \%$ of rac-69. Intermediate 68 was further explored for the synthesis of rac-4 as shown in the scheme-11.

Scheme-11 : (Ono et al, Heterocycles 1994, 37, 181-185)

Reagents and conditions : a) $\mathrm{BF}_{3}-\mathrm{OEt}_{2},-78{ }^{\circ} \mathrm{C}, 68 \%$ (68) and $11 \%$ (69); b) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}$; c) Ts Cl , pyridine, $86 \%$ overall; d) $\mathrm{NaBH}_{4}, \mathrm{DMSO}$; e) $\mathrm{Ac}_{2} \mathrm{O}$, pyridine, $96 \%$; f) $\mathrm{AlCl}_{3}$, $\mathrm{EtSH} ;$ g) MOMCl, $\mathrm{NaH}, 18$-crown-6, $\mathrm{CH}_{3} \mathrm{CN}, 71 \%$ overall; h) $2 \mathrm{~N} \mathrm{NaOH}, \mathrm{MeOH}, 88 \%$; i) (i) $\mathrm{PCC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$; (ii) $\mathrm{Ph}_{3} \mathrm{P}^{+} \mathrm{CHMe}_{2} \mathrm{I}, \mathrm{NaH}, \mathrm{DMSO}, 26 \%$ overall; j) $2 \mathrm{~N} \mathrm{HCl}, \mathrm{i}-\mathrm{PrOH}, 61 \%$; k) $\mathrm{Ce}\left(\mathrm{NH}_{4}\right)_{2}\left(\mathrm{NO}_{3}\right)_{6}, \mathrm{H}_{2} \mathrm{O}$, THF, $23 \%$.

Later on, similar strategy was used for the synthesis of rac-curcudiol 65, raccurcuphenol 3a and rac-curcuhydroquinone 3b. ${ }^{19}$

## Vyvyan's Approach : (Scheme-12 and 13, 2004) ${ }^{20}$

In this article, aromatic bisabolene skeleton 64 was prepared by Pd-catalyzed coupling of organozinc reagents with different aromatic rings. ${ }^{21}$ Alkenyl triflates were also coupled to the arylzinc reagents ${ }^{22}$ to prepare a few other aromatic bisabolenes.

Scheme-12 : (Vyvyan et al, J. Org. Chem. 2004, 69, 2461-2468)

Accordingly, organozinc reagents 84, prepared by reaction of the corresponding halides $\mathbf{8 3}$ with Rieke zinc in tetrahydrofuran, were treated with aryl bromides $\mathbf{8 5}$ using $\mathrm{Pd}(\mathrm{dppf}) \mathrm{Cl}_{2}$ as a catalyst to produce intermediates $\mathbf{8 6}$ and $\mathbf{7 8}$ in good yields (Scheme-13).

## Scheme-13

Reagents and conditions : a) $\operatorname{Pd}(d p p f) \mathrm{Cl}_{2}(c a t)$, THF, reflux, $71-81 \%$; b) dilute $\mathrm{HCl}, 89 \%$; c) CAN, MeCN: $\mathrm{H}_{2} \mathrm{O}, 83 \%$ from 86 and $98 \%$ from $\mathbf{3 b}$.

However, as methyl ether 86 couldn't be deprotected to synthesize rac-3b, intermediate $\mathbf{7 8}$ was further elaborated to $\mathrm{rac}-\mathbf{3 b}$ and $\mathrm{rac}-\mathbf{4}$ as shown in the scheme-13.

## Ono's Approach : $\left(\right.$ Scheme-14, 1995) ${ }^{23}$

87

88

3a

First enantioselective synthesis of (S)-curcuphenol 87, ( $S$ )-curcudiol 88 and $(R)$ curcuphenol 3a have been described, where enzymatic resolution of rac-89 using immobilized lipase in organic solvent had been used for the introduction of chirality at benzylic position and for this purpose, several commercially available lipases had been screened.

Scheme-14 : (Ono et al, Tetrahedron: Asymmetry 1995, 6, 1829-1832)

| No | Substrate (g) | Lipase | Products \% (\% ee) |  |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Rac-89 (0.2) | MY-30 (Candida cylindracea) | $(R)-89 ; 69(36)$ | $(S)-90 ; 27(80)$ |
| 2 | Rac-89 (0.25) | Immobilized Lipase (MY-30) | $(R)-89 ; 77(24)$ | $(S)-90 ; 22(85)$ |
| 3 | Rac-89 (0.2) | OF-360 (Candida cylindracea) | $(R)-89 ; 38(83)$ | $(S)-90 ; 60(51)$ |
| 4 | Rac-89 (0.2) | Immobilized Lipase (OF-360) | $(R)-89 ; 40(90)$ | $(S)-90 ; 52(58)$ |
| $5^{*}$ | $(S)-90$ | OF-360 | $(S)-89 ; 74(90)$ | $(R)-90 ; 16(30)$ |

* Optically active (S)-90 (80\% ee) was employed.

Intermediate ( $\boldsymbol{S}$ )-89, thus obtained, was further elaborated for the synthesis of the title compounds as described in the earlier synthesis of same (racemic) compounds. ${ }^{17}$

Serra's Approach : (Scheme-15 and 16, 2000) ${ }^{24}$

91

92

93

This particular publication reported the enantioselective synthesis of $(S)-(+)$ curcuphenol 87, ( $S$ )-(+)-xanthorhhizol 91, ( $S$ )-(-)-curcuquinone 92 and ( $S$ )-(+)curcuhydroquinone 93 using baker's yeast reduction of conjugated aldehyde 94 to enantiopure alcohols $\mathbf{9 5}$, which were useful chiral building blocks.

Scheme-15 : (Serra et al, J. Chem. Soc., Perkin Trans. 1 2000, 3758-3764)

For the synthesis of (S)-(-)-curcuquinone 92, the key intermediate 94c was prepared from 2-methylhydroquinone 96 by (i) $O$-methylation using dimethyl sulfate, (ii) acylation using $\mathrm{SnCl}_{4}$ as the Lewis acid, (iii) two carbon olefination of the resulting acetophenone using Wittig-Horner's protocol and (iv) reduction followed by Swern oxidation.

Intermediate $\mathbf{9 4} \mathbf{c}$ on baker's yeast reduction provided alcohol $\mathbf{9 5 c}$ with $98 \%$ ee. The hydroxyl functionality of $\mathbf{9 5} \mathbf{c}$ was then transformed to iodide 99, which was further coupled with isobutenyl magnesiumbromide using copper(I) iodide to afford bisabolene framework 100. This on ceric ammonium nitrate oxidation furnished ( $S$ )-(-)-curcuquinone 92. Using similar reaction sequence, other title compounds were also synthesized.

Scheme-16 : (Serra et al, J. Chem. Soc., Perkin Trans. 1 2000, 3758-3764)

Reagents and conditions : a) (i) $\mathrm{Me}_{2} \mathrm{SO}_{4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$, acetone; (ii) $\mathrm{AcCl}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{SnCl}_{4}, 78 \%$; b) $(\mathrm{EtO})_{2} \mathrm{POCH}_{2} \mathrm{COOEt}, \mathrm{NaH}, 14 \%$; c) (i) DIBAL, THF; (ii) (COCl$)_{2}, \mathrm{DMSO}_{2} \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{Et}_{3} \mathrm{~N}, 70 \%$; d) baker's yeast, $6 \mathrm{~d}, 56 \%$; e) (i) TsCl , pyridine, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$; (ii) NaI, acetone, reflux, 89\%; f) $\mathrm{Me}_{2} \mathrm{C}=\mathrm{CHMgBr}, \mathrm{CuI}(\mathrm{cat}), \mathrm{THF}, 89 \%$; g) CAN, aq. MeCN, $87 \%$.

## Shishido's Approach : (Scheme-17, 2000) ${ }^{5}$

101

102

First enantioselective synthesis of heliannuol D 101 and A 102 via (S)curcuquinone 92 using enzymatic transesterification of diol 106 as the key reaction, has been described here.

Thus, the key prochiral diol 106 was prepared by Heck reaction between 103 and 104, followed by ozonolytic cleavage and reductive workup using $\mathrm{NaBH}_{4}$, which on Candida antactica lipase (CAL)-catalyzed transesterification ${ }^{25}$ in diethyl ether using vinyl acetate as an acetyl donor at room temperature produced the optically active monoacetate
$\mathbf{1 0 7}$ in $87 \%$ yield. (S)-Curcuquinone $\mathbf{9 2}$ was synthesized from 107 via sulfone $\mathbf{1 1 0}$ following a few steps, which was further utilized for the syntheses of titled heliannuols.

Scheme-17 : (Shishido et al, J. Chem. Soc., Perkin Trans. 1 2000, 1807-1808)

Reagents and conditions : a) $\mathrm{Pd}(\mathrm{OAc})_{2}, \mathrm{Ph}_{3} \mathrm{P}$, $i-\mathrm{Pr}_{2} \mathrm{NEt}, \mathrm{DMF}, 80^{\circ} \mathrm{C}, 90 \%$; b) $\mathrm{O}_{3}, \mathrm{MeOH}, \mathrm{NaBH}_{4}$,
 DMSO, $60{ }^{\circ} \mathrm{C}$; e) (i) $\mathrm{LiAlH}_{4}, \mathrm{THF}$, rt, 99\%; (ii) PhSSPh, $n-B u_{3} P$, pyridine, rt, 99\%; f) $m C P B A$, $\mathrm{KHCO}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 97 \%$; g) (i) n-BuLi, HMPA, THF, $\mathrm{Me}_{2} \mathrm{C}=\mathrm{CHCH}_{2} \mathrm{Br},-78{ }^{\circ} \mathrm{C}$, $98 \%$; (ii) $\mathrm{Na}-\mathrm{Hg}$ (5\%), $\mathrm{NaHPO}_{4}, \mathrm{MeOH}$, sonication, rt, $84 \%$; $h$ ) $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}, \mathrm{MeCN}, \mathrm{MeOH}, \mathrm{H}_{2} \mathrm{O}, \mathrm{rt}, 96 \%$.

Heinz Dotz' Approach : (Scheme-18, 2005) ${ }^{26}$
In this latest synthesis of (-)-curcuquinone 4, Sharpless asymmetric epoxidation was used to introduce chirality and chromium mediated $[3+2+1]$ benzannulation for overall skeletal formation.

Scheme-18 : (Heinz Dotz et al, J. Org. Chem. 2005, 70, 3745-3748)

Reagents and conditions: a) (D)-(-)-DIPT, Ti(O-i-Pr) $)_{4}, T B H P, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{MS} 4 \AA,-20^{\circ} \mathrm{C}, 1 \mathrm{~h}, 87 \%$; b) $\mathrm{NaBH}_{3} \mathrm{CN}^{2} \mathrm{BF}_{3}-\mathrm{OEt}_{2}, \mathrm{THF}, \mathrm{rt}, 86 \%$; c) $\mathrm{NaIO}_{4}, \mathrm{Bu}_{4} \mathrm{NIO}_{4}, \mathrm{H}_{2} \mathrm{O}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}, 95 \%$; d) $\mathrm{CBr}_{4}$, $\mathrm{PPh}_{3}, \mathrm{Zn}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, r t, 60 \%$; e) $n$-BuLi, THF, $-78^{\circ} \mathrm{C}$ to $\mathrm{rt}, 99 \%$; f) $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 55^{\circ} \mathrm{C}, 2.5 \mathrm{~h}, \mathrm{CAN}, \mathrm{H}_{2} \mathrm{O}$, $0^{\circ} \mathrm{C}, 30 \mathrm{~min}, 80 \%$.

Thus, this convergent synthesis was commenced from commercially available geraniol 111, which on asymmetric epoxidation provided epoxide $\mathbf{1 1 2}$ in $95 \%$ ee. This epoxide on Lewis-acid mediated reductive ring opening followed by oxidative glycol cleavage using sodium periodate provided aldehyde 114, which was transformed to terminal acetylene $\mathbf{1 1 6}$ using Corey-Fuch's protocol in $60 \%$ yield. Finally, synthesis of (-)4 was accomplished in $80 \%$ yield in a benzannulation ${ }^{27}$ reaction of chromium carbene complex 117 with chiral terminal acetylene 116. The reaction occurred with complete regioselectivity, which on direct oxidative work-up provided (-)-curcuquinone 4.

Chapter-2, Section-2 : Enantiospecific Synthesis of(-)-Parvifoline \& (+)-Isoparvifolinone : Friedel-Craft's Acylation Approach For Benzocyclooctane Ring Formation

### 2.2.1 Introduction

The main structural features that challenge the synthesis of (-)-parvifoline ${ }^{1}$ are; a) benzocyclooctene framework formation with an acid sensitive deconjugated double bond, and b) presence of a chiral center at the non-functionalized benzylic position.

1

2

3

As mentioned earlier, there have been four total syntheses of rac-parvifoline reported, but not a single asymmetric synthesis has been attempted. Further, the interest in employing the renewable resources of the nature for the synthesis of natural products has led to identification of $(R)-(+)$-citronellal as the key synthon, which is abundantly available both from plants and of synthetic origin, and using which synthesis of laevigatin ${ }^{2}$ and $\beta$ herbertenol ${ }^{3}$ have been accomplished. This particular section describes the enantiospecific synthesis of (-)-parvifoline 1 and (+)-isoparvifolinone 2 (via xanthorrhizol 3) using intramolecular Friedel-Craft's acylation as the key step.

### 2.2.2 Present work : Results and discussion

Encouraged by the results achieved in the enantiospecific synthesis of (+)- $\beta$ herbertenol, ${ }^{3}$ it was envisioned that $(R)-(+)$-citronellal could very well serve as the source of chirality for the enantiospecific synthesis of (-)-parvifoline 1 via phenol intermediate $\mathbf{3}$, which is also a naturally isolated one from the rhizomes of Curcuma xanthorrhiza Roxb, named xanthorrhizol. ${ }^{4}$ Diol 6 would be the ideal precursor for the synthesis of 3. Further, phenol $\mathbf{3}$ could be utilized for the synthesis of (+)-isoparvifolinone 2 and (-)-parvifoline $\mathbf{1}$, via cyclooctenone intermediate 4 , which in turn could be synthesized from $Z-\alpha, \beta$ unsaturated ester 5. As depicted in the retrosynthetic analysis, diol $\mathbf{6}$ could be obtained enantiospecifically from $(R)-(+)$-citronellal via $\alpha$-hydroxy enone 7 (Scheme-1).

## Scheme-1

Thus, to start with, ( $R$ )-(+)-citronellal ( $98 \%$ ee) was converted to the enone intermediate $\mathbf{8}$ using literature method. ${ }^{5}$

## Scheme-2

Reagents and conditions : a) formalin (35\%), piperidine acetate, $110^{\circ} \mathrm{C}, 4 \mathrm{~h}$; b) NaOMe (cat), methylacetoacetate, MeOH, reflux, 5 h, 45\% overall.

Accordingly, it was first treated with formalin solution (35\%) in the presence of piperidine acetate as the base to give exomethylene derivative $\mathbf{9}$, which on treatment with methylacetoacetate in the presence of catalytic amount of sodium methoxide, underwent Michael addition, aldol condensation and decarboxylation in one pot to deliver the required enone 8 as a 1: 1 mixture of diastereomers in $45 \%$ overall yield (Scheme-2). It was characterized by comparison of it's IR and NMR spectral data with those of the reported one. ${ }^{5}$

Next, to have the phenolic hydroxyl group in $\mathbf{3}$ at appropriate position, it was required to functionalize the $\alpha$-position of enone $\mathbf{8}$ regiospecifically, which also has an additional olefin functionality in it's side chain. For this purpose, Rubottom's protocol ${ }^{6}$ of $\alpha$-hydroxylation was resorted to, which involves formation of the enol ether of the corresponding carbonyl compound, that could be achieved regiospecifically as described by House et al, ${ }^{7}$ followed by peracid oxidation. Mechanistically this involves epoxide formation of an enol ether double bond by mCPBA, which rearranges to relieve the ring strain with migration of the silyl group to give the corresponding silylated $\alpha$-hydroxy ketone. Accordingly, enone $\mathbf{8}$ was silylated using lithium diisopropylamine as the base and chlorotrimethylsilane as the silylating agent in dry THF at $-78^{\circ} \mathrm{C}$.

## Scheme-3

Reagents and conditions : a) (i) LDA, THF, $-78^{\circ} \mathrm{C}, 1.5 \mathrm{~h}, \mathrm{TMSCl},-78^{\circ} \mathrm{C}$ to $r$ t, 5 h ; b) (i) mCPBA, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to rt, 10 h ; (ii) dilute $\mathrm{HCl}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 12 \mathrm{~h}, 70 \%$ overall.

Under these conditions, enone $\mathbf{8}$ gave kinetically favored enol ether 10, which was further oxidized using mCPBA ( $85 \%$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $0{ }^{\circ} \mathrm{C}$ to provide trimethylsilyl ether of $\alpha$-hydroxyenone 7. It was hydrolyzed without it's purification using dilute HCl to furnish $\alpha$-hydroxyenone 7 as a mixture of diastereomers in $70 \%$ overall yield (Scheme-3). As it
was planned to aromatize the cyclic system to the corresponding aromatic unit, the newly generated chiral centers of $\mathbf{8}$ (and $\mathbf{7}$ also) were of no consequence, and thus no attempt was made to separate or characterize them. Formation of $\mathbf{7}$ was confirmed by it's IR, NMR and mass spectral data, and further ascertained by it's elemental analysis.

Absorption at $3435 \mathrm{~cm}^{-1}$ in it's IR spectrum, and one proton doublet of a doublet at $\delta 4.32(J=12.9,5.8 \mathrm{~Hz})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum indicated the presence of a secondary hydroxyl group, which was further evident from a methine resonance at $\delta 69.5$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. It's ${ }^{1} \mathrm{H}$ NMR spectrum revealed one proton triplet at $\delta 5.07(J=7.0 \mathrm{~Hz})$, assigned to the side chain olefin proton; which also exhibited two singlets at $\delta 1.59$ and 1.67 , each integrated for three protons, assigned to the two methyl groups associated with the isopropylidene functionality. Presence of enone functionality was evident from a resonance at $\delta 200.1$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum, characteristic of the conjugated ketone carbonyl group. Finally, $\alpha$-hydroxy enone 7 was confirmed by it's mass spectrum, which revealed a peak of $(\mathrm{M}+1)^{+}$at 223 , and by it's elemental analysis also, which was in good agreement with the calculated values.

Keeping in mind the substitution pattern in phenol 3, the next job was to introduce a methyl group over enone carbonyl group, which was achieved by 1,2-addition using methyl magnesium iodide to provide the diol 6 as a mixture of diastereomers in $95 \%$ yield. However, it was possible to separate out two spots by flash column chromatography, which were further characterized to be a mixture of diastereomers by it's ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectral data, but as we were about to destroy the newly generated chiral centers in the next step of the synthesis, no attempt was made to separate or characterize the diastereomers and their ratios as well (Scheme-4).

Additional methyl group singlet at $\delta 1.22(3 \mathrm{H})$ and upfield shift of the olefin protons involved in the cyclohexene ring at $\delta 5.45-5.61(\mathrm{~m})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum were indicative of the required transformation, which was further evident from a quaternary carbon resonance at $\delta 71.2$ apart from a methine doublet at $\delta 73.3$, characteristic of carbons attached to an hydroxyl group, in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Diol 6 was finally ascertained by it's mass spectrum, which exhibited a peak at $261(\mathrm{M}+\mathrm{Na})^{+}$and by it's elemental analysis also.

Diol 6 would be the ideal substrate for the synthesis of phenol 3, as it contains a secondary hydroxyl group, which on oxidation might undergo elimination of tertiary hydroxyl group with concomitant aromatization. This was achieved under Swern oxidation
conditions, as other oxidizing agents (DMP, PDC) resulted in lower yield of the crude unstable oxidized product, which was difficult to purify.

## Scheme-4

Reagents and conditions : a) MeMgI, diethyl ether, $0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 12 \mathrm{~h}, 95 \%$; b) (i) oxalyl chloride, DMSO, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}$, then diol 6, $30 \mathrm{~min}, \mathrm{Et}_{3} \mathrm{~N},-78^{\circ} \mathrm{C}$ to $\mathrm{rt}, 5 \mathrm{~h}$; (ii) methanesulfonylchloride, $E t_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to rt, 3 h , reflux, 5 h ; (iii) KOH , methanol, reflux, $7 \mathrm{~h}, 47 \%$ overall; c) $\mathrm{K}_{2} \mathrm{CO}_{3}$ dimethyl sulfate, acetone, reflux, $12 h, 86 \%$.

Accordingly, diol 6 was subjected to Swern oxidation ${ }^{8}$ and as anticipated, it resulted in a mixture of the required phenol derivative 3 together with unstable $\alpha$-hydroxy ketone intermediate (as indicated by TLC), which could not be isolated and furnished only impure phenol 3 after column purification, in very poor yields ( $25 \%$ ). At this stage, tertiary hydroxyl group elimination of crude $\alpha$-hydroxy ketone would have increased the overall yield of phenol 3 and to confirm this, crude product obtained after Swern oxidation was subjected to mesylation, which provided phenol $\mathbf{3}$ along with it's unseparable mesyl ester. Therefore, the crude product was further hydrolyzed using potassium hydroxide as the base under refluxing methanol to furnish the required phenol intermediate, i. e. xanthorrhizol ${ }^{4} 3$ in $47 \%$ isolated yield for three steps (Scheme-4).

An hydroxyl group absorption at $3411 \mathrm{~cm}^{-1}$ in it's IR spectrum and an aromatic singlet at $\delta 153.7$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum suggested the phenolic nature of the intermediate 3. Further, ${ }^{1} \mathrm{H}$ NMR spectrum revealed resonances at $\delta 6.56-6.65(\mathrm{~m})$, integrated for two protons and $\delta 6.98(\mathrm{~d}, J=7.7 \mathrm{~Hz})$ for one proton; were assigned to the aromatic protons. Also, a triplet (with further unresolved couplings) at $\delta 5.05(J=7.1 \mathrm{~Hz}$, $1 \mathrm{H})$ and two singlets at $\delta 1.55(3 \mathrm{H})$ and $1.66(3 \mathrm{H})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum, were assigned to the isopropylidene functionality $\left(-\mathrm{CH}=\mathrm{CMe}_{2}\right)$, present in the side chain. Phenol $\mathbf{3}$ was
finally confirmed by it's mass spectrum, which exhibited a peak of $\mathrm{M}^{+}$at 218 , and by it's elemental analysis also.

Further, phenol $\mathbf{3}$ was protected as it's methyl ether $\mathbf{1 1}$ in $86 \%$ yield, using dimethyl sulfate and potassium carbonate in refluxing acetone (Scheme-4). Absence of hydroxyl absorption at $3411 \mathrm{~cm}^{-1}$ in it's IR spectrum and presence of a three proton singlet at $\delta 3.83$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum suggested the success of required transformation, which was further evident from a methyl quartet at $\delta 55.1$, characteristic of a methoxy group, in it's ${ }^{13} \mathrm{C}$ NMR spectrum. It was further ascertained by it's mass spectrum, which revealed a peak at $255(\mathrm{M}+\mathrm{Na})^{+}$and by it's elemental analysis as well.

Having secured the aromatic unit 11, the next major task was to check the feasibility of Friedel-Craft's acylation for benzocyclooctenone formation and for this purpose, it was required to have a cis-conjugated ester 5. To synthesize ester 5, double bond of the anisole derivative $\mathbf{1 1}$ had to be chopped off oxidatively to have an aldehyde, over which two carbon Wittig olefination would have served the purpose. To get the selectivity for Z-double bond isomer, Ando's modification ${ }^{9}$ of Horner-Emmon's olefination was preferred, which uses diarylphosphono esters $\mathbf{1 2 - 1 4}$ in the presence of an inexpensive base, such as Triton B or NaH in THF for the synthesis of trisubstituted conjugated ester with high $Z$-selectivity, and thus use of excess of expensive and hygroscopic 18-Crown-6 required in Still's method of cis-olefination ${ }^{10}$ was avoided.
$(\mathrm{PhO})_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{COOEt}(\mathbf{1 2}),(\mathrm{o}-\mathrm{MePhO})_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{COOEt}$ (13) or (o-iPr-PhO) $)_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{COOEt}$ (14)

The reaction is believed to proceed as shown in scheme-5, that is, the phosphorylstabilized carbanion attacks the carbonyl in a stepwise manner to give erythro and threo adducts, which then decompose via four centered transient species $\mathbf{1 5}$ and 16, to the corresponding olefin products. The stereochemistry is determined by a combination of the stereoselectivity in the C-C bond forming step and reversibility of the intermediate adducts. Thus, conditions that favor more of the erythro adduct, lead to more of the $Z$-isomer. In the case of $\alpha$-methyl esters, it is advised to use phosphonates with bulky substituents in the aryl ring and to carry out reaction at lower temperature for greater $Z$-selectivity.

## Scheme-5

And for oxidative double bond cleavage, Lemieux-Johnson's reagent ${ }^{11}$ was opted, which uses sodium periodate in combination with osmium tetroxide (catalytic) in aqueous dioxane. Aldehyde 18 obtained by this method was immediately subjected to two carbon olefination as described by Ando et al, which resulted in the requisite trisubstituted conjugated ester 5, with exclusive selectivity for cis-isomer, but only in $50 \%$ isolated yield (Scheme-6).

Conjugated ester 5 was characterized completely by it's IR, NMR, mass spectral data and further ascertained by it's elemental analysis. IR spectrum of the isolated product showed absorptions at $1705 \mathrm{~cm}^{-1}$ and $1644 \mathrm{~cm}^{-1}$; characteristic of the $\alpha, \beta$-unsaturated esters. This was further supported by it's ${ }^{1} \mathrm{H}$ NMR spectrum, which revealed a resonance for one olefin proton at $\delta 5.87$ (td, $J=7.6,1.4 \mathrm{~Hz}$ ). The downfield shift of this olefin proton indicated it's conjugation with an electron withdrawing substituent. Further, three proton triplet at $\delta 1.23(J=7.1 \mathrm{~Hz})$ and two proton quartet at $\delta 4.14(J=7.1 \mathrm{~Hz})$ were indicative of the presence of an ethyl ester functionality, which was further evident by a carbonyl resonance at $\delta 168.1$ (s) and an additional methylene doublet at $\delta 60.0$, in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Absence of the singlets due to two methyl groups associated with the isopropylidene functionality of $\mathbf{1 1}$, at $\delta 1.54$ and 1.68 in the ${ }^{1} \mathrm{H}$ NMR spectrum of the isolated product, which instead revealed a three proton doublet at $\delta 1.86(J=1.3 \mathrm{~Hz})$, assigned to $\mathrm{CH}=\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{COOEt}$, supported the proposed intermediate. The doublet was due
to allylic coupling with the adjacent olefin proton (at $\delta$ 5.87), which showed a triplet of doublet ( $J$ value of doublet in both the cases was quite close). Finally, unsaturated ester 5 was confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+1)^{+}$at 291 and (M$\mathrm{OEt})^{+}$at 245 , and by it's elemental analysis also.

## Scheme-6

Reagents and conditions : a) $\mathrm{OsO}_{4}$ (cat), NMO ( $50 \%$ in water), acetone, $r$ t, 24 h ; b) $\mathrm{NaIO}_{4}$ supported over silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, 3 h ; c) $\mathrm{NaH}(60 \%), 13, \mathrm{THF},-78^{\circ} \mathrm{C}, 3 \mathrm{~h}, 85 \%$ overall.

The lower overall yield of the conjugated ester 5 might be attributed to the unstability of the aldehyde intermediate 18, which was synthesized by Lemieux-Johnson's reagent in 24 hours, and to improve the yields, it was decided to go via more stable diol intermediate 17. It was prepared by treating the olefin 11 with NMO ( $50 \%$ ) in the presence of catalytic amount of osmium tetroxide in acetone at room temperature for 24 hours, which without purification was subjected to glycol cleavage using sodium periodate supported over silica gel in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature. Under these conditions, reaction took just 3 hours for completion and as anticipated, the resultant aldehyde afforded ester $\mathbf{5}$ in improved overall yields, that is $85 \%$ under previously described reaction conditions.

After successful introduction of the ester functionality, the stage was set to check the crucial ring closure. Keeping in mind the reactivity of methacrylic acid derivatives towards polymerization, the corresponding acid derivative, obtained after hydrolysis of intermediate 5 using KOH as the base in refluxing methanol, was treated with oxalyl chloride at $0{ }^{\circ} \mathrm{C}$ for 3 hours, and the resultant acid chloride was immediately subjected to Friedel-Craft's acylation. ${ }^{12}$ Thus, it was treated with anhydrous aluminium chloride in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $-20{ }^{\circ} \mathrm{C}$ and stirred at room temperature for 10 hours to provide the required benzocyclooctenone intermediate 4 in $40 \%$ overall yield (Scheme-7).

## Scheme-7

Reagents and conditions : a) (i) $\mathrm{KOH}, \mathrm{MeOH}$, reflux, 3 h ; (ii) oxalyl chloride, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}, 3 \mathrm{~h}$; (iii) anhydrous $\mathrm{AlCl}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-20^{\circ} \mathrm{C}$ to rt, $10 \mathrm{~h}, 40 \%$ overall.

IR spectrum of the isolated product indicated the presence of an enone functionality by exhibiting absorptions at $1710 \mathrm{~cm}^{-1}$ and $1624 \mathrm{~cm}^{-1}$. Cyclisation of the side chain over aromatic ring was indicated by presence of only two aromatic resonances at $\delta 6.64$ (s) and $7.41(\mathrm{~d}, J=0.8 \mathrm{~Hz})$, characteristic of tetra substituted aromatic ring with para distributed protons. This was further supported by it's ${ }^{13} \mathrm{C}$ NMR spectrum, which revealed four quaternary signals at $\delta 124.5,141.3,143.0$ and 160.6 . Moreover, downfield shift of one olefin proton at $\delta 6.44(\mathrm{td}, J=9.0,1.4 \mathrm{~Hz})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum was indicative of the formation of an eight membered ring with double bond still in conjugation with the carbonyl group, which in turn, was in conjugation with the aromatic ring. It was finally confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+1)^{+}$at 245 and by it's elemental analysis also, which was found to be in good agreement with the calculated values.

Pleased with the benzocyclooctenone framework formation, the remaining task was deoxygenation of the enone carbonyl group, which should be performed under conditions that doesn't lead to the migration of the double bond in conjugation with the aromatic ring. Therefore, use of acidic conditions and thus Clemmenson reduction methodology was not of proper choice. Therefore, it was thought to try out Huang-Minlon modification ${ }^{13}$ of Wolff-Kishner reduction for the required purpose. Accordingly, enone 4 was treated with hydrazine hydrate in the presence of KOH in diethylene glycol at $210{ }^{\circ} \mathrm{C}$ for 12 h , which instead of deoxygenated product (i.e. parvifoline methyl ether), resulted in 19, formation of which was proposed on the basis of it's NMR spectral data (Scheme-8).

## Scheme-8

19

Reagents and conditions : a) hydrazine monohydrate, hydrazine dihydrochloride, $\mathrm{KOH}, 150^{\circ} \mathrm{C}, 3$ h, $210^{\circ} \mathrm{C}, 12 \mathrm{~h}, 50 \%$.

The ${ }^{1} \mathrm{H}$ NMR spectrum of the isolated product revealed a three proton triplet at $\delta$ $1.08(J=7.6 \mathrm{~Hz})$ and a two proton quartet at $\delta 2.51(J=7.6 \mathrm{~Hz})$, which suggested the presence of an ethyl group attached to an olefin carbon atom. Also, apart from a three proton singlet at $\delta 2.20$ (characteristic of $\mathrm{Ar}-\mathrm{CH}_{3}$ ), it's ${ }^{1} \mathrm{H}$ NMR spectrum exhibited a three proton singlet at $\delta 1.88$, which indicated the presence of an allylic methyl group. Formation of $\mathbf{1 9}$ was also supported by it's ${ }^{13} \mathrm{C}$ NMR spectrum, which showed total 16 carbon resonances. There were eight carbon resonances in the olefin region of the spectrum, out of which only two were methine resonances (at $\delta 108.4$ and 125.4), while the rest of the six resonances indicated quaternary carbon atoms. This indicated tetrasubstitution pattern of the olefin functionality, present in the cyclohexene ring. Further, ${ }^{13} \mathrm{C}$ NMR spectrum didn't exhibited any carbonyl resonance. Mass spectrum further supported the formation of $\mathbf{1 9}$ by exhibiting $(\mathrm{M}+1)^{+}$at 231 and also $\left(\mathrm{M}-\mathrm{CH}_{2} \mathrm{CH}_{3}\right)^{+}$at 201. From all these spectral data, structure 19 was proposed for the isolated product.

The plausible pathway of the formation of $\mathbf{1 9}$ has been proposed in the scheme-8, that is via, (i) retro aldol reaction to provide 20; (ii) intramolecular aldol condensation of 20 to form highly facile six membered ring unit of conjugated aldehyde 21 and (iii)
deoxygenation of aldehyde to the methyl group, to provide 19. However, unstability of the intermediate and also due to time constraint, $\mathbf{1 9}$ was not completely characterized.

Failure of Wolff-Kishner deoxygenation protocol for the required transformation necessitated to proceed via an alcohol intermediate 22 (Scheme-9), which has previously been reported by Joseph-Nathan et al ${ }^{14}$ for the synthesis of rac-parvifoline 1. However, in this case, it was planned to synthesize via isoparvifolinone methyl ether 23, and thus to utilize the cyclic enone $\mathbf{4}$ for the enantiospecific synthesis of (+)-isoparvifolinone $\mathbf{2}$ as well.

## Scheme-9

Thus, synthesis of isoparvifolinone methyl ether $\mathbf{2 3}$ was undertaken, for which enone 4 was selectively reduced under Luche reduction ${ }^{15}$ conditions to provide the corresponding unstable benzyl alcohol, which on pyridinium chlorochromate ${ }^{16}$ oxidation, underwent 1,3-ketone transposition to give $\mathbf{2 3}$ in $60 \%$ overall yield (Scheme-10).

It was characterized by it's IR and NMR spectral data comparison with those of reported one ${ }^{14}$ and was found to be in good agreement. The characteristic features in it's NMR spectra were; a singlet at $\delta 6.76(1 \mathrm{H})$, attributed to the cyclooctenone olefin proton; three proton doublet due to allylic methyl group at $\delta 2.01(\mathrm{~d}, J=1.4 \mathrm{~Hz})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum, and a carbonyl resonance at $\delta 204.0$ (s) in it's ${ }^{13} \mathrm{C}$ NMR spectrum.

Intermediate 23 was finally subjected to methyl ether deprotection using $\mathrm{BBr}_{3}$ in $60 \%$ yield, to complete the first enantiospecific synthesis of (+)-isoparvifolinone 2 (Scheme-10).

## Scheme-10

Reagents and conditions : a) (i) $\mathrm{CeCl}_{3}-7 \mathrm{H}_{2} \mathrm{O}, \mathrm{NaBH}_{4}, \mathrm{MeOH}, 0{ }^{\circ} \mathrm{C}, 30 \mathrm{~min}$; (ii) PCC over silica gel, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 2 \mathrm{~h}, 60 \%$ overall; b) $\mathrm{BBr}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 1 \mathrm{~h}, 60 \%$; c) $\mathrm{H}_{2} / 10 \% \mathrm{Pd} / \mathrm{C}, \mathrm{MeOH}, 24$ h, then $\mathrm{NaBH}_{4}, 30 \mathrm{~min}, 55 \%$.

This chemically synthesized isoparvifolinone $\mathbf{2}$ was in complete agreement with the naturally isolated one ${ }^{1 \mathrm{~b}} \mathrm{mp} 157-158{ }^{\circ} \mathrm{C}$ and specific rotation : $[\alpha]^{25}{ }_{\mathrm{D}}+850\left(c 1, \mathrm{CHCl}_{3}\right)$. $\left\{\right.$ lit. ${ }^{\text {b }} \mathrm{mp} 157-158{ }^{\circ} \mathrm{C}$; specific rotation : $\left.[\alpha]^{25}{ }_{\mathrm{D}}+854\left(c 1, \mathrm{CHCl}_{3}\right)\right\}$. The sign and value of the specific rotation suggested the configuration and optical purity of the product obtained.

Intermediate 23 was, further, hydrogenated using $10 \% \mathrm{Pd} / \mathrm{C}$ (catalytic) in methanol followed by sodium borohydride reduction in the same pot, which afforded the previously reported alcohol $\mathbf{2 2}^{14}$ in 55\% overall yield (Scheme-10). Intermediate $\mathbf{2 2}$ was confirmed by it's IR and NMR spectral data comparison with those of reported, ${ }^{14}$ and was found to be in good agreement. It's IR spectrum showed absorption at $3616 \mathrm{~cm}^{-1}$ and $3454 \mathrm{~cm}^{-1}$, attributed to an hydroxyl group. Absence of enone functionality was evident from it's ${ }^{13} \mathrm{C}$ NMR spectrum, which in addition revealed a methine doublet at $\delta 75.4$, indicated the presence of a secondary hydroxyl group. However, it's ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra suggested high diastereomeric purity of the product obtained, but as these two centers were to be destroyed in the next step of the synthesis, no attempt was made to characterize the isomer.

Finally, to complete the synthesis of (-)-parvifoline 1, secondary hydroxyl group elimination was attempted under the conditions, described by Nathan et al. ${ }^{14}$ Accordingly, $\mathbf{2 2}$ was treated with $p$-toluenesulfonylchloride in pyridine at $-4^{\circ} \mathrm{C}$ for 3 days. Surprisingly, it ended up in the corresponding tosylate only, which was then heated at $100^{\circ} \mathrm{C}$ in pyridine to furnish the required (-)-parvifoline methyl ether $\mathbf{2 4}$ in 65\% yield (Scheme-11).

## Scheme-11

Reagents and conditions : a) p-toluenesulfonylchloride, pyridine, $-4^{\circ} \mathrm{C}, 3$ days, then $100^{\circ} \mathrm{C}, 10 \mathrm{~h}$, 65\%; b) EtSLi, DMF, $105^{\circ} \mathrm{C}, 24$ h, $90 \%$.

Formation of $\mathbf{2 4}$ was confirmed by it's IR and NMR spectral data comparison with those of the literature values ${ }^{14}$ and was found to be in good agreement. It showed specific rotation $[\alpha]^{25}{ }_{\mathrm{D}}-200\left(c 1, \mathrm{CHCl}_{3}\right)$.

Methyl ether of $\mathbf{2 4}$ was finally deprotected using (highly nucleophilic and relatively nonbasic) lithium thioethoxide in DMF at $105^{\circ} \mathrm{C}$ to complete the synthesis, which indeed delivered the final product, that is, (-)-parvifoline $\mathbf{1}$ in $90 \%$ yield.

It was characterized by it's IR and NMR spectral data comparison with those of reported one. ${ }^{1 \text { a }}$ It's IR spectrum showed absorption at $3602 \mathrm{~cm}^{-1}$, attributed to the phenolic hydroxyl group. It's ${ }^{1} \mathrm{H}$ NMR spectrum revealed characteristic doublets at $\delta 3.01$ and 3.51 with same coupling constant $(J=18.3 \mathrm{~Hz})$, assigned to $\mathrm{Ar}-\mathrm{CH}_{2}-\mathrm{C}(\mathrm{Me})=\mathrm{CH}$; and a triplet at $5.34(J=7.0 \mathrm{~Hz})$, assigned to the only olefin proton present in the cyclooctene ring. Specific rotation of the product was $[\alpha]^{25}{ }_{\mathrm{D}}-168\left(c 1.73, \mathrm{CHCl}_{3}\right)\left\{\right.$ lit. ${ }^{1 \mathrm{a}}[\alpha]^{25}{ }_{\mathrm{D}}-173(c 1.73$, $\left.\left.\mathrm{CHCl}_{3}\right)\right\}$, which also suggested the optical purity of the product and confirmed it's absolute configuration as well.

### 2.2.3 Conclusions

(-)-Parvifoline has been synthesized enantiospecifically, starting from naturally occurring $(R)-(+)$-citronellal as the source of chirality, using intramolecular Friedel-Craft's acylation as the key step. (+)-Isoparvifolinone has also been synthesized on similar lines.

### 2.2.4 Experimental

## 6-Hydroxy-4-((R)-6-methylhept-5-en-2-yl)cyclohex-2-enone (7)

A 100 mL round bottom flask equipped with a magnetic stir bar and a condenser was charged with diisopropylamine ( $3.83 \mathrm{~g}, 37.90 \mathrm{mmol}$ ) and dry THF ( 50 mL ) under $\mathrm{N}_{2}$ atmosphere, and cooled to $-78{ }^{\circ} \mathrm{C}$. To this mixture, n -BuLi ( 1.6 M solution in hexane) ( $22.4 \mathrm{~mL}, 36.4$ mmol ) was added dropwise and stirred for 10 min , followed by dropwise addition of the conjugated ketone $\mathbf{8 ( 6 \mathrm { g } , 2 9 . 1 \mathrm { mmol } ) \text { in dry }}$ THF ( 10 mL ). The reaction mixture was stirred for 1.5 h at $-78^{\circ} \mathrm{C}$ and then quenched with chlorotrimethylsilane ( $3.48 \mathrm{~g}, 32 \mathrm{mmol}$ ). It was allowed to come to $0{ }^{\circ} \mathrm{C}$ within 5 h and quenched with saturated $\mathrm{NaHCO}_{3}$ solution ( 200 mL ). The mixture was extracted with pet. ether ( $50 \mathrm{~mL} \times 3$ ), and the combined organic layers were washed with brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure to give 8 g of crude silyl enol ether, which was confirmed by it's ${ }^{1} \mathrm{H}$ NMR spectrum and used as such for the next step.

The crude silyl enol ether was taken in a 250 mL single neck round bottom flask, to which $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL})$ was added, followed by addition of $5 \% \mathrm{NaHCO}_{3}$ solution (100 mL ). The reaction mixture was cooled to $0^{\circ} \mathrm{C}$ and mCPBA ( $5.25 \mathrm{~g}, 30.5 \mathrm{mmol}$ ) was added to it portionwise. It was stirred at room temperature for 10 h and then diluted using saturated $\mathrm{NaHCO}_{3}$ solution ( 100 mL ), followed by extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL}$ x 3). The combined organic layers were washed with saturated $\mathrm{Na}_{2} \mathrm{SO}_{3}$ solution ( 150 mL ), saturated $\mathrm{NaHCO}_{3}$ solution ( 150 mL ), brine $(150 \mathrm{~mL})$, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. It was then taken in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(75 \mathrm{~mL})$ in a 250 mL round bottom flask, cooled to $0{ }^{\circ} \mathrm{C}$ and to this was added 1.5 M HCl solution ( 75 mL ). It was stirred at room temperature for 12 h , extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(75 \mathrm{~mL} \times 2)$, the combined organic layers were washed with water ( 75 mL ), brine ( 75 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, 96 : 4) to give hydroxy enone 7 $(4.5 \mathrm{~g})$ as a colourless oil (mixture of diastereomers).

## 2-Methyl-5-((R)-6-methylhept-5-en-2-yl)cyclohex-3-ene-1,2-diol (6)

A flame dried 250 mL round bottom flask equipped with a magnetic stir bar and a condenser was charged with Mg turnings ( $2.73 \mathrm{~g}, 112.2$ mmol) and diethyl ether ( 100 mL ), under $\mathrm{N}_{2}$ atmosphere. MeI (15.9 $\mathrm{g}, 112.2 \mathrm{mmol}$ ) was added to it at $0{ }^{\circ} \mathrm{C}$ and stirred at room temperature for 2 h . To this Grignard reagent, enone $7(8.3 \mathrm{~g}, 37.4$ mmol ) was added using diethyl ether ( 20 mL ) at $0^{\circ} \mathrm{C}$ and stirred at room temperature for 12 h . It was quenched using saturated $\mathrm{NH}_{4} \mathrm{Cl}$ solution $(100 \mathrm{~mL})$ at 0 ${ }^{\circ} \mathrm{C}$ and extracted using ethyl acetate ( 50 mL x 3 ). The combined organic layers were washed with brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, $9: 1$ ) to give diol $6(8.5 \mathrm{~g})$ as a colourless oil. (two spots separated, each was found to be a mixture of diastereomers)

(R)-2-Methyl-5-(6-methylhept-5-en-2-yl)phenol (3)

A 1 lit round bottom flask equipped with a magnetic stir bar and a condenser was charged with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(170 \mathrm{~mL})$ followed by oxalyl chloride ( $26.4 \mathrm{~g}, 208 \mathrm{mmol}$ ), under $\mathrm{N}_{2}$ atmosphere, and cooled to $-78{ }^{\circ} \mathrm{C}$. Dimethyl sulfoxide ( $32.5 \mathrm{~g}, 416 \mathrm{mmol}$ ) was added to it dropwise, during which internal temperature was maintained below $-60{ }^{\circ} \mathrm{C}$. After complete addition, the reaction mixture was stirred for 15 min and then diol $6(15 \mathrm{~g}, 63 \mathrm{mmol})$ was added using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(50 \mathrm{~mL})$ dropwise, and stirred for 30 min . Finally, the reaction mixture was quenched using triethylamine ( $89.3 \mathrm{~g}, 882 \mathrm{mmol}$ ) at $-78^{\circ} \mathrm{C}$ and was brought to room temperature within 5 h. Water ( 200 mL ) was added to it, followed by extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL} x \mathrm{3})$. The combined organic layers were washed with brine ( 150 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The crude product was carried forward without it's column purification.

The crude $\alpha$-hydroxy ketone was taken in a 1 lit two neck round bottom flask and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 150 mL ) was added to it. The reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and triethylamine ( $38.3 \mathrm{~g}, 378 \mathrm{mmol}$ ) was added, followed by dropwise addition of methanesulfonylchloride $(21.6 \mathrm{~g}, 189 \mathrm{mmol})$. The reaction mixture was stirred at room temperature for 3 h and then refluxed for additional 5 h . Finally, it was quenched with saturated $\mathrm{NaHCO}_{3}$ solution ( 150 mL ), and extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 100 mL x 3). The combined organic layers were washed using brine ( 200 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The crude product, which contains phenol 3 as well as it's mesyl ester, was taken in methanol ( 150 mL ), and KOH pellets
$(10.61 \mathrm{~g}, 18.9 \mathrm{mmol})$ was added. It was refluxed for 7 h . Methanol was removed under reduced pressure and the reaction mixture was diluted using water ( 150 mL ), and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $100 \mathrm{~mL} \times 3$ ). The combined organic layers were washed using brine (200 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue obtained was chromatographed using flash silica gel (pet. ether : EtOAc, $96: 4$ ) to provide phenol $\mathbf{3}(6.5 \mathrm{~g})$ as a colourless oil.

## ( $R, Z$ )-Ethyl-6-(3-methoxy-4-methylphenyl)-2-methylhept-2-enoate (5)

A 50 mL round bottom flask was charged with olefin 11 ( 3 g , 12.9 mmol ) and acetone ( 25 mL ). It was cooled to $0^{\circ} \mathrm{C}$ and $\mathrm{OsO}_{4}(0.1 \mathrm{M}$ solution in toluene) ( 1 mL ) was added to it, followed by $50 \%$ NMO (in water) ( $4.6 \mathrm{~mL}, 19.4 \mathrm{mmol}$ ). The reaction mixture was stirred at room temperature for 24 h and then diluted with water $(50 \mathrm{~mL})$, followed by extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $50 \mathrm{~mL} \times 3$ ). The combined organic layers were washed with brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The crude diol was diluted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 150 mL ), and added $\mathrm{NaIO}_{4}$ supported over silica gel ( $10 \%$ ) (61 $\mathrm{g}, 28.5 \mathrm{mmol}$ ). It was stirred for 3 h and filtered through a short pad of celite, washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{~mL} x 4)$. The combined organic layers were evaporated under reduced pressure and the crude aldehyde, thus, obtained was subjected to two carbon olefination.
$\mathrm{NaH}(60 \%)(0.62 \mathrm{~g}, 15.5 \mathrm{mmol})$ was taken in a 100 mL two neck round bottom flask and THF ( 20 mL ) was added to it under, $\mathrm{N}_{2}$ atmosphere. The reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and phosphonate $\mathbf{1 3}(7 \mathrm{~g}, 19.4 \mathrm{mmol})$ was added to it using THF ( 10 mL ). The reaction mixture was stirred at room temperature for 15 min and then cooled to $-78^{\circ} \mathrm{C}$. To this was added crude aldehyde using THF ( 10 mL ) at $-78{ }^{\circ} \mathrm{C}$, stirred for 3 h more at the same temperature and quenched using saturated $\mathrm{NH}_{4} \mathrm{Cl}$ solution ( 100 mL ). The solution was extracted using ethyl acetate ( $50 \mathrm{~mL} \times 3$ ). The combined organic layers were washed with brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using (pet. ether : EtOAc, $95: 5$ ) to provide cis-olefin $5(3.2 \mathrm{~g})$ as a colourless oil.

## (R, Z)-2-Methoxy-3,6,10-trimethyl-9,10-dihydorbenzo[8]annulen-5(8H)-one (4)

The Z-ester $5(2.5 \mathrm{~g}, 8.62 \mathrm{mmol})$ was taken in a 50 mL round bottom flask and methanol ( 25 mL ) was added to it, followed by addition of 5 M KOH solution ( 3.5 mL ). The reaction mixture was refluxed for 3 h and acidified using $5 \% \mathrm{HCl}$ solution ( 75 mL ). It was, then, extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $50 \mathrm{~mL} \times 3$ ); the combined organic layers were washed

with brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The crude acid was taken in a 100 mL round bottom flask and to this was added $\mathrm{CH}_{2} \mathrm{Cl}_{2}(25$ mL ), under $\mathrm{N}_{2}$ atmosphere. It was, then, cooled to $0^{\circ} \mathrm{C}$ and oxalyl chloride ( $2.2 \mathrm{~g}, 17.2 \mathrm{mmol}$ ) was added to it, dropwise. The reaction mixture was stirred at the same temperature for 3 h and then $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was evaporated under reduced pressure, at room temperature. The crude acid chloride was taken in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{~mL})$ and cooled to $-20{ }^{\circ} \mathrm{C}$, followed by addition of anhydrous $\mathrm{AlCl}_{3}(1.26 \mathrm{~g}, 9.5 \mathrm{mmol})$, under $\mathrm{N}_{2}$ atmosphere. It was allowed to come to room temperature within 10 h , followed by quenching using $10 \% \mathrm{HCl}$ solution ( 50 mL ). It was then extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $30 \mathrm{~mL} \times 3$ ). The combined organic layers were washed with water ( 60 mL ), brine ( 60 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatogrphed using flash silica gel (pet. ether : EtOAc, 98 : 2) to provide cyclic enone $4(0.85 \mathrm{~g})$ as a white solid.

## (R)-4-Ethyl-7-methoxy-1,3,6-trimethyl-1,2-dihydronaphthalene (19)

Enone $4(0.1 \mathrm{~g}, 0.41 \mathrm{mmol})$ was taken in diethylene glycol ( 5 mL ) in a 25 mL single neck round bottom flask, equipped with a magnetic stir bar and a reflux condenser. Hydrazine monohydrate $(0.1 \mathrm{~g}, 2 \mathrm{mmol})$, hydrazine dihydrochloride ( $0.2 \mathrm{~g}, 2 \mathrm{mmol}$ ) and $\mathrm{KOH}(85 \%)(0.6 \mathrm{~g}, 9.1 \mathrm{mmol})$ was added to it at room temperature and the reaction mixture was heated at $150{ }^{\circ} \mathrm{C}$ for 3 h , and then at $210^{\circ} \mathrm{C}$ for additional 12 h. The reaction mixture was cooled to room temperature and diluted using water ( 25 mL ), and extracted with ethyl acetate ( $25 \mathrm{~mL} \times 3$ ). The combined organic layers were washed using water ( 50 mL ), brine ( 50 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (per. ether : EtOAc, 99 : 1) to give $19(47 \mathrm{mg})$ as a pale yellow oil.

Isoparvifolinone methyl ether (23) ${ }^{14}$

Enone $4(0.4 \mathrm{~g}, 1.64 \mathrm{mmol})$ was taken in a 25 mL round bottom flask and methanol ( 5 mL ) was added to it, followed by $\mathrm{CeCl}_{3}{ }^{-}$ $7 \mathrm{H}_{2} \mathrm{O}(1.22 \mathrm{~g}, 3.28 \mathrm{mmol})$. It was cooled to $0{ }^{\circ} \mathrm{C}, \mathrm{NaBH}_{4}$ ( 62 $\mathrm{mg}, 1.64 \mathrm{mmol}$ ) was added to it portionwise and stirred for 30 min , the reaction mixture was diluted using saturated $\mathrm{NH}_{4} \mathrm{Cl}$ solution ( 30 mL ) and extracted using ethyl acetate ( $30 \mathrm{~mL} \times 3$ ). The combined organic layers were washed with brine ( 50 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and
concentrated under reduced pressure. The crude alcohol was taken in a 50 mL round bottom flask together with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{~mL})$, under $\mathrm{N}_{2}$ atmosphere. Pyridinium chlorochromate over silica gel (1: 1) ( $2 \mathrm{~g}, 4.92 \mathrm{mmol}$ ) was added to it, followed by 2 h stirring. Finally, it was filtered over celite and was washed using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 100 mL ). The combined organic layers were concentrated under reduced pressure and the residue was chromatographed using flash silica gel (pet. ether : EtOAc, 97 : 3) to provide $23(0.24 \mathrm{~g})$ as a pale yellow oil.

Chapter-2, Section-3 : Enantiospecific Synthesis of(-)-Curcuquinone \& (-)-Parvifoline Ring Closing Metathesis Approach

### 2.3.1 Introduction

After successfully synthesizing (-)-parvifoline $\mathbf{1}^{1}$ enantiospecifically from ( $R$ )-(+)citronellal using intramolecular Friedel-Craft's acylation as the key step as described in section-1, attention towards even shorter and high yielding route led to explore about the feasibility of formation of benzocyclocyclooctene framework under Grubb's ring closing metathesis conditions and simultaneous installation of the acid sensitive deconjugated double bond of parvifoline at the appropriate location. Further, structural similarities between the intermediates obtained from $(R)-(+)$-citronellal (chapter-2, section-2) and (-)curcuquinone 2 (the simplest monocyclic sesquiterpene benzoquinone, which was isolated from the Pseudoterogorgia rigid ${ }^{2}$ ) encouraged to utilize the same starting material for the enantiospecific synthesis of $\mathbf{2}$, which has also been shown to possess antibacterial activity and more importantly, proven to be a versatile chiral building blocks for the synthesis of related important natural products, such as heliannuols. ${ }^{3}$ The present section deals with the ring closing metathesis approach towards synthesis of (-)-parvifoline $\mathbf{1}$ and enantiospecific synthesis of (-)-curcuquinone 2.

1

2

Olefin metathesis reactions are gaining increasing importance due to introduction of new and efficient catalysts during last decade ${ }^{4}$ and have been successfully used for the preparation of both carbocyclic as well as heterocyclic ring systems. More importantly, medium and large rings ${ }^{5}$ have been constructed efficiently and thus it has become a reliable tool for natural product synthesis.

Olefin metathesis is a disproportionation process involving bond formation, bond breakage and reorganization. It was first reported by Anderson and Merckling in 1955, where Ti (IV) metal catalysts were used for polymerization of norbornene. ${ }^{6}$

Schrock's catalyst, 3

Grubbs' $2^{\text {nd }}$ generation catalyst, 5

Grubbs' $1^{\text {st }}$ generation catalyst, 4

Hoveyda-Grubbs' catalyst, 6

## Scheme-1

Later on, after introduction of Mo and Ru based catalysts by Schrock ${ }^{7}$ and Grubbs, ${ }^{8}$ which are air stable and are tolerant to diverse functional groups, olefin metathesis has become popular in organic synthesis as well.

Scheme-1 depicts the postulated mechanism for ring closing metathesis reaction, which involves an iterative process of $[2+2]$ cycloaddition and cycloreversion between the olefins, metal alkylidene and metallocyclobutene species.

### 2.3.2 Present work : Results and discussion

As depicted in the retrosynthetic analysis (Scheme-2), ring closing metathesis could be performed over diolefin intermediate 7 to achieve the benzocyclooctene ring, and thus parvifoline 1. Secondary hydroxyl group oxidation of diol $\mathbf{8}$ would have resulted in the required phenol derivative 7, which in turn could be synthesized by Grignard addition over enone 9. Enone 9 could be synthesized from tertiary allylic alchol 10 in a few steps, which has already been synthesized enantiospecifically utilizing $(R)-(+)$-citronellal as the source of chirality, as discussed in chapter-2, section-2.

## Scheme-2

Accordingly, the synthesis commenced from diol intermediate 10, which was treated with acetyl chloride in pyridine at room temperature, to protect it's secondary hydroxyl group selectively, which indeed resulted in the requisite product 11 in $85 \%$ isolated yield (Scheme-3).

Presence of a strong stretching band at $1729 \mathrm{~cm}^{-1}$, characteristic of an ester carbonyl group, in it's IR spectrum was indicative of the success of the attempted reaction. Further ${ }^{1} \mathrm{H}$ NMR spectrum exhibited a one proton multiplet ranged over $\delta 4.88-4.91$, assigned to $\mathrm{CHOC}(\mathrm{O}) \mathrm{CH}_{3}$, which appeared at $\delta 3.72-3.74(\mathrm{~m}, 1 \mathrm{H})$ in the diol intermediate 10. The downfield shift of this particular proton suggested the formation of acetate 11, which was also confirmed by a quaternary carbon resonance at $\delta 170.5$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum, indicating the presence of an ester carbonyl group. Finally acetate $\mathbf{1 1}$ was ascertained by it's mass spectrum and elemental analysis also.

## Scheme-3

Reagents and conditions: a) pyridine, acetyl chloride, $0^{\circ} \mathrm{C}$ to $\mathrm{rt}, 12 \mathrm{~h}, 85 \%$; b) $\mathrm{PCC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, r t, 7$ h, $80 \%$.

As discussed in the retrosynthetic analysis, the next crucial reaction to be performed was carbonyl transposition to have an enone $\mathbf{9}$, which would be useful in the second olefin side chain introduction at the required position. 1,3-carbonyl transposition by pyridinium chlorochromate protocol would have served this purpose.

Pyridinium chlorochromate is reported to be effective in 1,3-carbonyl transposition of tertiary allylic alhohols $\mathbf{1 3}$, which was first reported by Babler et al, ${ }^{9}$ where two carbon homologation of various ketones $\mathbf{1 2}$ have been achieved by addition of vinyl Grignard over keto functionality, followed by treatment of the resulting tertiary allylic alcohols $\mathbf{1 3}$ with PCC (Scheme-4a).

However, use of PCC for 1,3-carbonyl transposition was generalized by Dauben et al in 1977, ${ }^{10}$ where various conjugated cyclic ketones 15 were also converted to the transposed 3 -alkyl- $\alpha, \beta$-unsaturated ketones $\mathbf{1 7}$ via tertiary allylic alcohols $\mathbf{1 6}$ in excellent yields (Scheme-4b).

## Scheme-4

Working on similar lines, allyl alcohol 11 was treated with PCC in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature for 7 hours to afford the requisite enone 9 (as a mixture of diastereomers) in 80\% yield (Scheme-3).

The IR spectrum of the single isolated product 9 didn't show any absorption at 3444 $\mathrm{cm}^{-1}$, indicated the absence of tertiary hydroxyl group, which also revealed absorptions at $1739 \mathrm{~cm}^{-1}$ and $1675 \mathrm{~cm}^{-1}$, characteristic of an ester carbonyl (-OAc) and a conjugated carbonyl group, respectively. It's ${ }^{1} H$ NMR spectrum showed only one proton multiplet ranged over $\delta 5.83-5.87$, which was assigned to the only olefin proton in the cyclohexene ring. The downfield shift of this signal indicated allylic rearrangement of the double bond and presence of an enone functionality. Also, signal due to a proton attached to the carbon atom bearing acetate group further shifted downfield at $\delta 5.41-5.47(\mathrm{~m}, 1 \mathrm{H})$ supported this fact. Presence of one proton triplet at $\delta 5.03(J=7.1 \mathrm{~Hz})$, characteristic of the side chain olefin proton, indicated no cyclisation of the side chain over cyclohexene ring. A carbonyl resonance at $\delta 199.5$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum further supported the presence of a conjugated carbonyl group. Enone 9 was finally confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+1)^{+}$at 279 and by it's elemental analysis also, which was in good agreement with the calculated values.

To install a second olefin side chain for the metathesis reaction, it was required to introduce methallyl group over enone $\mathbf{9}$ at the carbon bearing carbonyl group. Accordingly, enone 9 was treated with methallyl magnesium chloride, generated separately in THF, but resulted in the recovery of starting material. So it was thought of doing the same reaction in
diethyl ether, which also met with the failure. This might be attributed to the reactivity of methallyl Grignard reagents towards self coupling. Finally, reaction was carried out under Barbier conditions, according to which it was treated with methallyl chloride and magnesium in THF at $0{ }^{\circ} \mathrm{C}$ for 24 h to provide the required diol 8 (as a mixture of diastereomers) in $90 \%$ yield (Scheme-5).

## Scheme-5

Reagents and conditions : a) Mg , methallyl chloride, THF, $0^{\circ} \mathrm{C}, 24 \mathrm{~h}, 90 \%$.

Intermediate $\mathbf{8}$ was characterized by it's IR and NMR spectral data. Absence of stretching band at $1675 \mathrm{~cm}^{-1}$ in the IR spectrum of the isolated product suggested absence of the carbonyl functionality. This was further supported by upfield shift of the only olefin proton in the cyclohexene ring ranged over $\delta 5.44-5.48$ as a multiplet, in it's ${ }^{1} \mathrm{H}$ NMR spectrum. Further, IR spectrum of the product $\mathbf{8}$ didn't show any absorption of an ester carbonyl group at $1739 \mathrm{~cm}^{-1}$, suggested deprotection of the $O$-acetate functionality. There were additional absorption bands at $3414 \mathrm{~cm}^{-1}$ in the IR spectrum, which suggested the presence of hydroxyl groups. Both of these facts were confirmed by it's ${ }^{13} \mathrm{C}$ NMR spectrum, which didn't show any characteristic carbonyl resonances of an ester or a conjugated enone at $\delta 170.2$ and 199.5, respectively. Further, upfield shift of the signal for proton attached to the carbon bearing secondary hydroxyl group at $\delta 3.93-3.96(\mathrm{~m}, 1 \mathrm{H})$ supported acetate group deprotection. Presence of additional methylene protons at $\delta$ 4.73$4.75(\mathrm{~m}, 1 \mathrm{H})$ and 4.87-4.89 ( $\mathrm{m}, 1 \mathrm{H}$ ) in it's ${ }^{1} \mathrm{H}$ NMR spectrum, suggested the introduction of methallyl group, which was confirmed by the presence of olefin resonances at $\delta$ 110.4, 112.7 and 115.2 in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Diol $\mathbf{8}$ was finally ascertained by it's mass spectrum and it's elemental analysis as well.

At this stage, intermediate $\mathbf{8}$ also could have been subjected for ring closing metathesis, but to minimize the number of steps after metathesis reaction, it was thought to aromatize the intermediate $\mathbf{8}$ to the required phenol derivative $\mathbf{7}$ first and then to go for metathesis, which also minimizes the risk of deconjugated double bond migration into conjugation of the resultant aromatic ring.

## Scheme-6

Reagents and conditions : a) DMP, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to $\mathrm{rt} 4 \mathrm{~h}, 85 \%$; b) (i) $\mathrm{Et}_{3} \mathrm{~N}$, methanesulfonyl chloride, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to rt, 3 h, then reflux, 5 h ; (ii) $\mathrm{KOH}, \mathrm{MeOH}$, reflux, $12 \mathrm{~h}, 79 \%$ for two steps.

To carry out aromatization of $\mathbf{8}$ to $\mathbf{7}$, secondary hydroxyl group of $\mathbf{8}$ should be oxidized first, so that the resulting enone $\mathbf{1 8}$ would help in the elimination of tertiary hydroxyl group and thus would result in aromatization, which also places the phenolic hydroxyl group in the required position. Accordingly, diol 8 was oxidized using DessMartin Periodinane ${ }^{11}$ reagent in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature to give the corresponding enone $\mathbf{1 8}$ in $85 \%$ yield (Scheme-6). Enone $\mathbf{1 8}$ was characterized by it's IR, mass and NMR spectral data.

It's IR spectrum exhibited absorption at $1667 \mathrm{~cm}^{-1}$, indicative of an enone carbonyl group, which was further confirmed by a resonance at $\delta 200.3$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Downfield shift of the signal attributed to the cyclohexene olefin proton from $\delta$ 5.44-5.48 (m) to $\delta$ 6.44-6.47 (m) in it's ${ }^{1} \mathrm{H}$ NMR spectrum, also suggested conjugation of the double bond with the carbonyl group. Enone $\mathbf{1 8}$ was finally confirmed by it's mass spectrum, which revealed a peak at $291(\mathrm{M}+1)^{+}$, and also by it's elemental analysis, which was in good agreement with the calculated values.

However, separation of diastereomers of intermediate 9 was attempted by preparative HPLC using chiral analytical OD column, which resulted in a failure. Also as the newly generated centers (in $\mathbf{1 1}, \mathbf{9}, 8$ and 18) would be destroyed at the later stages in the synthetic sequence, no attempt was made, further, to separate or characterize them.

Enone 18 was then subjected to mesylation conditions, that is, treatment with 3 equivalents of methanesulfonylchloride in presence of 6 equivalents of triethylamine as the base in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, which as anticipated resulted in tertiary hydroxyl group elimination with concomitant aromatization to afford phenol 7 along with unseparable corresponding mesyl ester. The crude product was immediately hydrolyzed by using potassium hydroxide as the base in refluxing methanol to afford the required phenol derivative $\mathbf{7}$ in $79 \%$ overall yield starting from $\mathbf{1 8}$ (Scheme-6).

Presence of an hydroxyl group absorption at $3393 \mathrm{~cm}^{-1}$ in it's IR spectrum suggested the formation of a phenol derivative, which was further supported by a characteristic phenolic quaternary carbon resonance in it's ${ }^{13} \mathrm{C}$ NMR spectrum at $\delta 152.5$ (s). It's ${ }^{1} \mathrm{H}$ NMR spectrum revealed two singlets at $\delta 6.60$ and 6.81 , each integrated for one proton, assigned to the para distributed aromatic protons. Also, one proton triplet at $\delta 5.06$ $(J=7.0 \mathrm{~Hz})$ was attributed to the isopropylidene olefin proton, while two singlets at $\delta 4.48$ $(1 \mathrm{H})$ and $4.76(1 \mathrm{H})$ were assigned to methallyl protons $\left(\mathrm{CH}_{2} \mathrm{C}(\mathrm{Me})=\mathrm{CH}_{2}\right)$, which was also confirmed by a methylene resonance at $\delta 111.4$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. The presence of methallyl side chain was further evident from a doublet at $\delta 3.20(J=4.7 \mathrm{~Hz}, 2 \mathrm{H})$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum, assigned to $\mathrm{Ar}-\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right)=\mathrm{CH}_{2}$, which was supported by a methylene resonance at $\delta 40.5$ in it's ${ }^{13} \mathrm{C}$ NMR spectrum. Other characteristic signals in it's ${ }^{1} \mathrm{H}$ NMR spectrum were : two singlets at $\delta 1.53$ and 1.67 , each integrating for three protons, were due to two methyl groups associated with isopropylidene side chain; a three proton doublet at $\delta 1.12(J=6.8 \mathrm{~Hz})$ was assigned to the only secondary methyl group present; a three proton singlet at $\delta 1.71$ was attributed to methallyl methyl group and a three proton singlet at $\delta 2.18$ was characteristic of a methyl group attached to the aromatic ring. Finally, phenol 7 was confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+1)^{+}$at 273 , and also by it's elemental analysis, found to be in good agreement with the calculated values.

The stage was then set for the crucial ring closing metathesis reaction over diolefin precursor 7 to complete the synthesis of parvifoline 1. Initially, Grubbs' first generation catalyst 4 was tried to achieve the required transformation, but without any success.

However the switchover to Grubbs' second generation catalyst $\mathbf{5}$ delightfully worked in hot toluene to provide the target molecule (-)-1 in $\mathbf{9 0 \%}$ isolated yield (Scheme-7).

## Scheme-7

Reagents and conditions : a) Grubbs' second generation catalyst 5, toluene, $80^{\circ} \mathrm{C}, 5 \mathrm{~h}, 90 \%$.

Formation of $\mathbf{1}$ was confirmed by it's IR and NMR spectral data comparison with those of the literature values. ${ }^{1}$ The solid compound obtained after preparative TLC had mp $85{ }^{\circ} \mathrm{C}\left\{\right.$ lit. ${ }^{1} 89-90{ }^{\circ} \mathrm{C}$, crystallized from hexane: acetone $\}$ and specific rotation $[\alpha]^{25}{ }_{D}-168$ (c $1.73, \mathrm{CHCl}_{3}$ ) $\left\{\right.$ lit. $\left.{ }^{1}[\alpha]^{25}{ }_{\mathrm{D}}-173\left(c 1.73, \mathrm{CHCl}_{3}\right)\right\}$. It's specific rotation suggested the optical purity of the final product, and ascertained it's configuration also.

After successfully synthesizing (-)-parvifoline 1, enantiospecific synthesis of (-)curcuquinone 2 was undertaken, for which intermediate 9 was envisioned as the key intermediate. Enone 9 was hydrolyzed using $\mathrm{K}_{2} \mathrm{CO}_{3}$ in methanol to the corresponding hydroxyenone, which was then subjected to Dess-Martin periodinane oxidation conditions, followed by base (triethylamine) treatment in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature. The crude product (believed to be corresponding hydroquinone) was immediately oxidized using ceric ammonium nitrate to provide the target molecule, that is, (-)-2 in $60 \%$ overall yield (Scheme-8). The physical and chemical properties of this synthetically obtained product were in good agreement with those of naturally isolated one. ${ }^{2}$

## Scheme-8

Reagents and conditions : a) (i) $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{MeOH}, \mathrm{rt}, 30 \mathrm{~min}$; (ii) $\mathrm{DMP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 2 \mathrm{~h}$; (iii) $\mathrm{Et}_{3} \mathrm{~N}$, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 3 \mathrm{~h}$; b) CAN, $\mathrm{CH}_{2} \mathrm{Cl}_{2}-\mathrm{H}_{2} \mathrm{O}, \mathrm{O}^{\circ} \mathrm{C}, 1 \mathrm{~h}, 60 \%$; c) acetyl chloride, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ to rt, overnight, $52 \%$ overall.

Further, to prove the intermediacy of the corresponding hydroquinone, the crude product obtained after DMP oxidation was treated with triethylamine and acetyl chloride to afford the diacetate derivative 19 in $52 \%$ isolated yield. It was completely characterized by it's IR, NMR and mass spectral analysis and ascertained by it's elemental analysis also.

### 2.3.3 Conclusions

Thus, (-)-parvifoline has been synthesized enantiospecifically from ( $R$ )-(+)citronellal as the source of chirality, using ring closing metathesis as the key step in $10 \%$ overall yield. (-)-Curcuquinone has also been successfully synthesized from ( $R$ )-(+)citronellal.

### 2.3.4 Experimental

## 2-Hydroxy-2-methyl-5-((R)-6-methylhept-5-en-2-yl)cyclohex-3-enylacetate (11)

 Diol 10 ( $3.4 \mathrm{~g}, 14.3 \mathrm{mmol}$ ) was taken in a 100 mL two neck round bottom flask, equipped with a magnetic stir bar, and pyridine ( 50 mL ) was added to it , under $\mathrm{N}_{2}$ atmosphere. The reaction mixture was cooled to $0^{\circ} \mathrm{C}$ and acetyl chloride $(2.25 \mathrm{~g}$, 28.6 mmol ) was added to it. The reaction mixture was stirred at room temperature for 12 h . Pyridine was evaporated under reduced pressure and the reaction mixture was diluted using ethyl acetate ( 100 mL ), washed using saturated $\mathrm{NaHCO}_{3}$ solution ( 50 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, 94 : 6) to give acetate $\mathbf{1 1}(3.4 \mathrm{~g})$ as a colourless oil (mixture of diastereomers).

## 2-Methyl-5-((R)-6-methylhept-5-en-2-yl)-4-oxocyclohex-2-enylacetate (9)

The alcohol $11(3.6 \mathrm{~g}, 12.86 \mathrm{mmol})$ was taken in a 100 mL two neck round bottom flask equipped with a magnetic stir bar, and $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{~mL})$ was added to it. The reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and pyridinium chlorochromate ( $5.54 \mathrm{~g}, 25.7 \mathrm{mmol}$ ) was added to it. The reaction mixture was stirred at room temperature for 7 h and diluted using diethyl

ether ( 50 mL ). The precipitated salt was then filtered through a short pad of celite, washed using diethylether ( $25 \mathrm{~mL} \times 3$ ), the solvent was evaporated on a rotary evaporator and the residue was chromatographed using flash silica gel (pet. ether : EtOAc, $97: 3$ ) to give enone $9(2.86 \mathrm{~g})$ as a colourless oil
(mixture of diastereomers).

## 3-Methyl-1-(2-methylallyl)-6-((R)-6-methylhept-5-en-2-yl)cyclohex-2-ene-1,4-diol (8)

A 100 mL two neck round bottom flask, equipped with a magnetic stir bar was charged with Mg turnings $(0.875 \mathrm{~g}$, 35.97 mmol ) and THF ( 30 mL ), under $\mathrm{N}_{2}$ atmosphere. The reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and enone $9(2 \mathrm{~g}, 7.19$ mmol ) was added to it using THF ( 10 mL ), followed by addition of methallyl chloride ( $3.26 \mathrm{~g}, 35.97 \mathrm{mmol}$ ). The reaction mixture was stirred at $0{ }^{\circ} \mathrm{C}$ for 24 h and quenched using saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(100 \mathrm{~mL})$. The extraction was carried out using EtOAc ( $50 \mathrm{~mL} \times 3$ ), the combined organic layers were washed using brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, $9: 1$ ) to give diol $\mathbf{8}(1.9 \mathrm{~g})$ as a colourless oil (mixture of diastereomers).

## (R)-2-Methyl-4-(2-methylallyl)-5-(6-methylhept-5-en-2-yl)phenol (7)

Enone 18 ( $0.5 \mathrm{~g}, 1.724 \mathrm{mmol})$ was taken in a 50 mL two neck round bottom flask, equipped with a magnetic stir bar. To this was added $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and cooled to $0{ }^{\circ} \mathrm{C}$, followed by dropwise addition of triethylamine $(0.872 \mathrm{~g}, 8.62 \mathrm{mmol})$ and mesyl chloride ( $0.79 \mathrm{~g}, 6.90 \mathrm{mmol}$ ), under $\mathrm{N}_{2}$ atmosphere. The reaction mixture was stirred at room temperature for 3 h and at reflux temperature for additional 5 h , quenched by addition of saturated $\mathrm{NaHCO}_{3}$ solution ( 50 mL ) and extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(25 \mathrm{~mL} \times 3$ ). The combined organic layers were washed using water ( 75 mL ), brine ( 75 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure.

The crude product was taken in $\mathrm{MeOH}(20 \mathrm{~mL})$ and to this was added $\mathrm{KOH}(0.2 \mathrm{~g}$, 3.56 mmol ), and refluxed for 12 h . Methanol was evaporated under reduced pressure and the reaction mixture was diluted with water $(50 \mathrm{~mL})$. The aqueous layer was extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(25 \mathrm{~mL} \times 3)$, the combined organic layers were washed using brine ( 50 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, $98: 2$ ) to give phenol 7 as a colourless oil ( 0.37 g ).

## (-)-Parvifoline (1) ${ }^{1}$

Phenol $7(0.25 \mathrm{~g}, 0.92 \mathrm{mmol})$ was taken in a 50 ml two neck round bottom flask, equipped with a magnetic stir bar and a condenser. Toluene ( 25 mL ) was added to it, followed by Grubbs' catalyst (second generation) 5 ( $78 \mathrm{mg}, 0.092 \mathrm{mmol}$ ), under $\mathrm{N}_{2}$ atmosphere, and stirred at $80{ }^{\circ} \mathrm{C}$ for 5 h . After completion of the reaction, toluene was removed under reduced pressure and the residue was chromatographed using flash silica gel (pet. ether : EtOAc, $99:$ 1), which further purified by preparative TLC (silica gel, pet. ether : EtOAc, $95: 5$ ) to furnish parvifoline $\mathbf{1}(0.18 \mathrm{~g})$ as a white solid.

## (-)-Curcuquinone (2) ${ }^{2}$

Enone $9(0.5 \mathrm{~g}, 1.80 \mathrm{mmol})$ was taken in a 50 mL round bottom flask along with methanol ( 5 mL ). To this was added anhydrous $\mathrm{K}_{2} \mathrm{CO}_{3}(0.372 \mathrm{~g}, 2.70 \mathrm{mmol})$ and stirred for 30 min . Methanol was evaporated under reduced pressure; the residue was diluted with water ( 30 mL ) and extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(30 \mathrm{~mL} \times 3$ ). The combined organic layers were washed using brine ( 50 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure.

The crude hydroxy enone was taken in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ in a 50 mL round bottom flask, under $\mathrm{N}_{2}$ atmosphere. To this was added Dess-Martin periodinane ( $0.762 \mathrm{~g}, 1.80$ mmol ) and stirred at room temperature for 2 h . It was then quenched using saturated $\mathrm{Na}_{2} \mathrm{SO}_{3}(15 \mathrm{~mL})$, followed by saturated $\mathrm{NaHCO}_{3}$ solution ( 15 mL ) and extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (30 mL x 3). The combined organic layers were washed using brine ( 30 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure.

The crude product was taken in a 50 mL round bottom flask. $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ was added to it, followed by triethylamine ( $1.10 \mathrm{~g}, 11.00 \mathrm{mmol}$ ) and stirred for 3 h at room temperature. $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and triethylamine was then evaporated under reduced pressure and crude hydroquinone was added to the solution of ceric ammonium nitrate $(6.90 \mathrm{~g}, 12.6$ mmol ) in water ( 30 mL ) using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$. It was then stirred at the same temperature for 1 h and diluted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(25 \mathrm{~mL})$. The organic layer was washed using saturated $\mathrm{NaHCO}_{3}$ solution ( 30 mL ), brine ( 30 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, $9: 1$ ) to give a yellow oil $2(0.25 \mathrm{~g})$.

Chapter-3: Synthesis of Herito $V_{\text {sing }}(\mathcal{R})-(+)$-Citronellal

### 3.1 Introduction

In 1987, Miles, ${ }^{1}$ et al have isolated an active toxin called heritol; a naturally occurring sesquiterpene from the sap of the mangrove plant Heritiera littoralis, which was shown to possess itchthytoxicity in ppm quantities to Tilapia nilotica fingerlings. Further in 1989, same authors have reported the isolation of a new natural pesticide, called heritonin (methyl ether derivative of heritol) from the same mangrove plant Heritiera littoralis, ${ }^{2}$ which also possesses similar kind of toxicity. Both of these compounds have a novel structure of cadinane sesquiterpene class containing $\alpha, \beta$-unsaturated $\gamma$-lactone moiety with an unusual oxygenation pattern.

1a, $R=A c$
2, $R=M e$, Heritonin

### 3.2 Structure determination

Miles' et al have established the structure and relative stereochemistry of $\mathbf{1}$ from it's spectral data and confirmed by it's single crystal X-ray analysis. Pure heritol was crystallized from methanol as a white needles (mp 271-272 ${ }^{\circ} \mathrm{C},[\alpha]^{25}+261.3$ ) and analyzed for $\mathrm{C}_{15} \mathrm{H}_{16} \mathrm{O}_{3}$ by HRMS, which indicated eight degree of unsaturation. The presence of aromaticity in the molecule was suggested by the fact that the molecular ion at m/e 244 was also the base peak. Also, fragmentations at m/e 216 (M-CO) ${ }^{+}$and m/e 215 $(\mathrm{M}-\mathrm{CHO})^{+}$were typical of a phenol.

The IR spectrum revealed absorptions at $3450 \mathrm{~cm}^{-1}$ and $1750 \mathrm{~cm}^{-1}$, indicating the presence of an hydroxyl group and an $\alpha, \beta$-unsaturated $\gamma$-lactone moiety. This was further supported by the UV (cyclohexane) absorption at 228 nm ( $\varepsilon$ 11950), characteristic of butenolide moiety. The ${ }^{1} \mathrm{H}$ NMR spectrum gave resonances at $\delta 6.85(\mathrm{~s}, 1 \mathrm{H})$ and $7.42(\mathrm{~s}$, 1 H ), for two isolated protons on an aromatic ring, which was further supported by UV spectrum that gave absorptions at 217, 285 and 305 nm . Moreover, ${ }^{1} \mathrm{H}$ NMR spectrum
provided evidence of the three nonequivalent methyl groups, by revealing resonances at $\delta$ $1.42(\mathrm{~d}, J=10.0 \mathrm{~Hz}, 3 \mathrm{H}), 2.18(\mathrm{~s}, 3 \mathrm{H})$ and $2.30(\mathrm{~s}, 3 \mathrm{H})$. Two of these resonances were as singlets, indicating their attachment to the quaternary carbons. The third methyl group with double multiplicity was assigned to be attached to a methine carbon. The ${ }^{1} \mathrm{H}$ NMR spectrum also gave signal for a methylene proton at $\delta 2.62(\mathrm{~m}, 1 \mathrm{H})$; a benzylic proton at $\delta$ $3.10(\mathrm{~m}, 1 \mathrm{H})$; a proton on a carbon bearing oxygen at $\delta 4.90(\mathrm{dd}, J=10.0,3.0 \mathrm{~Hz})$ and an hydroxyl proton at $\delta 5.22(\mathrm{~s}, 1 \mathrm{H})$. On acetylation of heritol, signal at $\delta 5.22$ disappeared, which further confirmed it's assignment as an hydroxylic proton.

Due to solubility problems with heritol, ${ }^{13} \mathrm{C}$ NMR spectrum was recorded for it's acetate 1a, which gave 17 resonances, indicating a molecule with no symmetry. Six aromatic resonances were observed at $\delta 121.1,126.5,129.2,130.2,141.9$ and 151.0 ppm . The intensity ratio of these lines and the presence of two lines of the same intensity at $\delta$ 121.1 and 130.2 suggested the symmetric ortho tetra substitution with two protons located in the para position. The two additional deshielded carbon resonances at $\delta 118.5$ and 155.8 were assigned to the $\alpha, \beta$-carbons of the butenolide moiety. A resonance at $\delta 79.3$ was assigned to the methine carbon attached to the oxygen involved in the lactone functional group. On the basis of the above spectroscopic data and a single crystal X-ray analysis, structure 1 was assigned to heritol. Although, the absolute stereochemistry at the centers C8 and C-10 could not be ascertained rigorously even by X-ray analysis, it was tentatively assigned to be $\boldsymbol{S}$ and $\boldsymbol{R}$ respectively, based on it's biosynthetic origin.

Structure of heritonin was elucidated by comparison of it's spectroscopic data with that of heritol and assigned structure $\mathbf{2}$, a methyl ether of heritol.

### 3.3 Synthesis of Heritol : A Review

There have been only three reports on the synthesis of rac-heritol $\mathbf{1}$ and heritonin 2. The first synthesis, reported by Irie et al, ${ }^{3}$ employed intramolecular Wittig-Horner reaction as the key step for the construction of butenolide moiety. The other synthesis was from this group by Chavan et al, ${ }^{4}$ where dihydroxylation over $\beta$, $\gamma$-unsaturated ester and eliminationlactonisation under basic conditions, were used as the key steps. Apart from these two syntheses, three methodologies have been developed by Chavan et al for the butenolide ring construction, using which synthesis of heritonin has been achieved. One of the methodology used $p$-toluenesulfonic acid for cyclisation of $\beta, \gamma$-dihydroxy ester to the butenolide; which was lateron modified by the same authors, where instead of $p$ TSA,
amberlyst-15 was used for similar cyclisations. The third methodology used ceric ammonium nitrate for one step oxidative cyclisation of $\beta, \gamma$-unsaturated acid to the butenolide rings. The latest synthesis of rac-heritonin 2 was reported by Silveira et al in 2004, where Lewis acid catalyzed reaction of various aryl acetic acid with allylsilanes to provide 4-alkyl-2-tetralone, which was further elaborated for the synthesis of heritonin 2 and it's C-8 epimer, was described.

## Irie's Approach (Scheme-1, 1990) ${ }^{3}$

The first synthesis of ( $\pm$ )-heritol 1 was reported by Irie et al utilizing tetralone 9 .

Scheme-1 : (Irie et al, Chem. Pharm. Bull. 1990, 38 (7), 1852-1856)

Reagents and conditions : a) (i) LAH ; (ii) $\mathrm{MnO}_{2}$; b) $\mathrm{CH}_{2}\left(\mathrm{COOMe}_{2}\right.$; c) $\mathrm{Me}_{2} \mathrm{CuLi}$, ether; d) (i) $\mathrm{KOH}, \mathrm{H}^{+}, 150-170^{\circ} \mathrm{C}$; (ii) $\mathrm{CH}_{2} \mathrm{~N}_{2}$; e) $\left.\mathrm{KOH} ; f\right)\left(\mathrm{COCl}_{2}, \mathrm{AlCl}_{3}, 35 \%\right.$ overall from 3; g) $\operatorname{PhI}(\mathrm{OAc})_{2}$, $67 \%$; h) $\mathrm{CH}_{3} \mathrm{CH}[\mathrm{C}(\mathrm{O}) \mathrm{Cl}] \mathrm{P}(\mathrm{O})(\mathrm{OEt})_{2}$; i) NaH , benzene, $1.5 \%$; j) $\mathrm{BCl}_{3}$.

The key step in the synthesis involves the construction of the butenolide moiety by intramolecular Wittig reaction (Wadsworth-Emmons modification), utilizing tetralone intermediate $\mathbf{9}$, which was prepared by the following series of reactions from methyl 3-methoxy-4-methylbenzoate $\mathbf{3}$. Thus, reduction of $\mathbf{3}$ with LAH followed by $\mathrm{MnO}_{2}$ oxidation of the resulting alcohol gave aldehyde 4 . Condensation of $\mathbf{4}$ with diethyl malonate furnished the benzal malonate 5. Methyl group was introduced by 1,4 -addition using lithium dimethylcuprate on $\mathbf{5}$ to provide diester $\mathbf{6}$, which was transformed to the ester $\mathbf{7}$ by alkaline hydrolysis of the diester 6 and concomitant decarboxylation at $150-170{ }^{\circ} \mathrm{C}$, followed by Arnt-Eistert one carbon homologation of the corresponding acid. It was hydrolyzed to the corresponding acid $\mathbf{8}$, which on treatment with oxalyl chloride followed by Friedel-Craft's acylation using aluminium chloride in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ furnished the tetralone 9 .

The overall yield of $\mathbf{9}$ from the methyl benzoate $\mathbf{3}$ was reported to be $35 \%$. Oxidation of 9 with iodoso benzene diacetate gave the stereoisomeric $\alpha$-hydroxy ketone 10 in $67 \%$ yield. Esterification of the hydroxy ketone 10 with $\alpha$-(diethylphosphono) propionylchloride gave the phosphonate 11 in good yield. Intramolecular EmmonsWadsworth reaction of the above phosphonate 11 with several bases in different solvents was sluggish and afforded inseparable mixture, consisting of $\mathbf{2}$ and it's C-8 epimer (10: 1 ratio respectively) in $1.5 \%$ overall yield. Demethylation of the heritol methyl ether 2 with boron trichloride afforded heritol $\mathbf{1}$ as a racemic mixture. The synthetic rac-heritol had mp $245-246{ }^{\circ} \mathrm{C}$, lower than that of optically active (+)-heritol 1. Heritol synthesized by above sequence of reactions was identical in all other respects with the natural product.

## Chavan's Approach (Scheme-2, 1991) ${ }^{4}$

The second synthesis of rac-heritol, reported by this group (Chavan et al) in 1991, used the same tetralone intermediate 9 (previously reported by Irie et $a l^{3}$ ) by a different route for butenolide ring construction, but in high yields compared to the previous one.

Accordingly, tetralone 9 was obtained starting from o-cresol methyl ether 12 by standard sequence of high yielding reactions. First of all, Friedel-Craft's acylation using succinic anhydride provided the keto acid 13 in $85 \%$ yield, which under Clemmenson's reduction condition underwent keto deoxygenation to give butyric acid derivative 14. Intermediate $\mathbf{1 4}$ on trifluoroacetic anhydride treatment underwent cyclisation to furnish tetralone $\mathbf{1 5}$ in $80 \%$ yield. 1,4-Ketone transposition and introduction of methyl group was
achieved as shown in the scheme-2 using standard functional group transformations to provide required tetralone 9 in $40 \%$ overall yield starting form o-cresol methyl ether $\mathbf{1 2}$.

Scheme-2 : (Chavan et al, Tetrahedron 1991 47, 5759-5768)

Reagents and conditions : a) succinic anhydride, $\mathrm{AlCl}_{3}, \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NO}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to $r t, 24 \mathrm{~h}, 85 \%$; b) $\mathrm{Zn}(\mathrm{Hg}), \mathrm{HCl}$, reflux; c) $\left(\mathrm{CF}_{3} \mathrm{CO}\right)_{2} \mathrm{O}, 0^{\circ} \mathrm{C}, 10 \mathrm{~min}, 80 \% ;$ d) $\mathrm{MeMgI}, \mathrm{Et}_{2} \mathrm{O}, \mathrm{H}^{+}$; e) $\mathrm{H}_{2}, 10 \% \mathrm{Pd} / \mathrm{C} ;$ f) $\mathrm{CrO}_{3}, \mathrm{AcOH}: \mathrm{EtCOOH}$ (1: 3), $40 \%$ overall; g) ethyl- $\alpha$-bromopropionate, $\mathrm{I}_{2}, \mathrm{Zn}, \mathrm{Et}_{2} \mathrm{O}, \mathrm{H}^{+}, 80 \%$; h) $\mathrm{OsO}_{4}$ (cat), $\mathrm{NMO}^{2} \mathrm{CH}_{3} \mathrm{CN}: \mathrm{H}_{2} \mathrm{O}$ (9: 1), $85 \%$; (i) MsCl, Et ${ }_{3} \mathrm{~N}$, DMAP, benzene, reflux, $15 \mathrm{~h}, 77 \%$; j) EtSH, $\mathrm{AlCl}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$.

This tetralone 9 on Reformatsky reaction with ethyl-2-bromopropionate, followed by acidic work-up gave $\beta, \gamma$-unsaturated ester 18 as a mixture of diastereomers; which on dihydroxylation using osmium tetroxide gave the key diol intermediate 19. Diol 19 on mesylation in refluxing benzene provided 3: 2 diastereomeric mixture of heritonin 2 and
it's C-8 epimer, which were separated by crystallization and deprotected using aluminium chloride-ethanethiol to give rac-1 and it's C-8 epimer as the sole product, respectively.

## Other butenolide ring construction protocols used for the synthesis of Heritol ${ }^{5-7}$

The first methodology reported by Chavan et al ${ }^{5}$ used $p$-toluenesulfonic acid for one pot dehydration as well as lactonisation purpose. Accordingly; $\beta$, $\gamma$-unsaturated ester 21 prepared from tetralone $\mathbf{2 0}$ by Reformatsky reaction, was dihydroxylated to give diol 22, which was then treated with $p$-toluenesulfonic acid in refluxing benzene to give required butenolide moiety 23 in high yields (Scheme-3). Using this methodology, heritonin and it's C-8 epimer has been synthesized in $90 \%$ overall yield. Instead of $p$ TSA, amberlyst- 15 has also been explored for the green synthesis of heritonin $\mathbf{2}$, heritol $\mathbf{1}$ and it's analogs. ${ }^{6}$

Scheme-3 : (Chavan et al, Tetrahedron Lett. 1992, 33, 4605-4608)

20

21

22

23
$\mathbf{R}^{\mathbf{1}}, \mathbf{R}^{\mathbf{2}}=\mathbf{H} / \mathrm{Me} / \mathbf{O M e} ; \mathbf{R}^{\mathbf{3}}, \mathbf{R}^{\mathbf{4}}=\mathbf{H} / \mathrm{Me}$ and $\mathbf{R}=\mathrm{Me} / \mathrm{Et}$.

The second method reported by Chavan et al, ${ }^{7}$ utilized ceric ammonium nitrate for oxidative cyclisation of the $\beta, \gamma$-unsaturated acid 24 to the required butenolides. Accordingly, acid 24, prepared by alkaline hydrolysis of the $\beta, \gamma$-unsaturated ester 21, on treatment with CAN in acetonitrile provided butenolides $\mathbf{2 3}$ in good to excellent yields (Scheme-4). Using this procedure, heritonin $\mathbf{2}$ was prepared from the corresponding acid in $36 \%$ yield.

Scheme-4 : (Chavan et al, J. Chem. Soc., Chem. Comm. 1994, 1101-1102)

$\mathbf{R}^{\mathbf{1}}, \mathbf{R}^{\mathbf{2}}=\mathbf{H} / \mathrm{Me} / \mathrm{OMe}$ and $\mathbf{R}^{\mathbf{3}}, \mathbf{R}^{4}=\mathbf{H} / \mathrm{Me}$

## Silveira's Approach (Scheme-5, 2004) ${ }^{8}$

Scheme-5 : (Silveira et al, Tetrahedron Lett. 2004, 45, 4077-4080)

Reagents and conditions : a) $\mathrm{AlCl}_{3}$, allyltrimethyl silane, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-20^{\circ} \mathrm{C}$ to reflux, $90 \mathrm{~min}, 41 \%$ overall; b) LDA, THF, $-78{ }^{\circ} \mathrm{C}, \mathrm{TMSCl}, 76 \%$; c) $\mathrm{ZnBr}_{2}$, $\alpha$-chloro- $\alpha$-phenylseleno-ethylpropionate, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}$ to rt; d) mCPBA, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}$ to rt, $41 \%$ overall; e) (i) $\mathrm{NaBH}_{4}, \mathrm{EtOH}, 0^{\circ} \mathrm{C}, 5 \mathrm{~min}$, rt, 1 h ; (ii) $12 \mathrm{~N} \mathrm{HCl}, 60^{\circ} \mathrm{C}, 40 \mathrm{~min}, 75 \%$ overall.

This particular approach differs from the rest in butenolide ring construction. They have mainly used two key steps, (i) $\mathrm{AlCl}_{3}$-mediated Friedel-Craft's reaction of aromatic acyl chlorides with allyltrimethylsilanes for the formation of $\beta$-tetralones ${ }^{9}$ and (ii) Lewis acid-mediated alkylation of the silylenolethers with $\alpha$-halo- $\alpha$-phenylselenoesters. ${ }^{10}$

Accordingly, aryl acid chloride 25 was treated with allyltrimethylsilane in the presence of anhydrous aluminium chloride to give $\beta$-tetralone 26, along with isomeric 27 in $41 \%$ overall yield. They were separated by repeated crystallization to give 26 in $25 \%$ isolated yield.

Further, for butenolide ring construction, enol ether 28, prepared from $\beta$-tetralone 26, was treated with $\alpha$-chloro- $\alpha$-phenylseleno-ethylpropionate in the presence of $\mathrm{ZnBr}_{2}$ to furnish $\gamma$-ketoester 29, which on mCPBA oxidation at $-78{ }^{\circ} \mathrm{C}$ provided $\alpha, \beta$-unsaturated ester $\mathbf{3 0}$ in $41 \%$ yield, together with $16 \%$ of it's isomeric trans-ester. Finally, ester $\mathbf{3 0}$ was cyclised upon reduction with $\mathrm{NaBH}_{4}$ followed by acid hydrolysis to give rac-heritonin 2 and it's C-8 epimer as a 3: 2 diastereomeric mixture in 75\% overall yield (Scheme-5).

### 3.4 Present work : Results and discussion

The present chapter primarily concerns with the asymmetric synthesis of heritol, a novel sesquiterpene lactone and thus confirmation of it's absolute configuration by the first enantiospecific synthesis using $(R)-(+)$-citronellal as the source of chirality.

The reasons behind undertaking it's synthesis were: (i) it was suggested that heritol is a potential biocompatible pesticide; (ii) difficulties associated with the introduction of chirality at the nonfunctionalised benzylic position; (iii) absolute configuration of heritol was not confirmed and (iv) interest in employing the renewable resources of the nature for the synthesis of natural products, therefore it was thought to synthesize enantiopure heritol, and for that purpose $(R)-(+)$-citronellal was found as the key synthon, which has already been utilized for the enantiospecific synthesis of laevigatin, ${ }^{11}(+)$-herbertenol, ${ }^{12}(-)-$ parvifoline, (+)-isoparvifolinone and (-)-curcuquinone (Chapter-2). The present work describes the first synthesis of enantiopure heritol starting from $(R)-(+)$-citronellal, utilizing the methodology developed in these laboratories, ${ }^{5}$ where $p$ TSA has been used as the catalyst for butenolide ring construction from the corresponding $\beta$, $\gamma$-unsaturated ester.

## Scheme-6

As delineated in the retrosynthetic analysis (Scheme-6), anisole derivative $\mathbf{3 2}$ was envisioned as the starting material (which has previously been prepared as described in the chapter-2, section-2 for the synthesis of (-)-parvifoline), for the preparation of the key tetralone intermediate 31. The remaining butenolide ring construction could be achieved by protocol reported earlier by this group for the synthesis of rac-heritol. ${ }^{4}$

Thus, the synthesis initiated from anisole 32, which was prepared enantiospecifically from $(R)-(+)$-citronellal ( $98 \%$ ee) as the chiron. Then, the next target was to synthesize tetralone intermediate 31. To get tetralone 31, it was thought to utilize the same acid intermediate, as reported by Irie et al, ${ }^{3}$ which might undergo cyclisation on either Friedel-Craft's acylation conditions or just by treatment with triflouroacetic anhydride. To have an acid intermediate 33, double bond of the anisole derivative $\mathbf{3 2}$ must be oxidatively chopped off and for this purpose Weinreb's protocol ${ }^{13}$ was adopted, according to which anisole derivative $\mathbf{3 2}$ was treated with Jones' reagent in the presence of osmium tetroxide (catalytic) in acetone at room temperature for 7 hours to furnish the required acid intermediate 33 in $82 \%$ isolated yield (Scheme-7).

## Scheme-7

Reagents and conditions : a) $\mathrm{OsO}_{4}(\mathrm{cat})$, Jones' reagent, acetone, $r t, 7 \mathrm{~h}, 82 \%$.

It was completely characterized by it's IR, NMR and mass spectral data. It's IR spectrum revealed a strong stretching band at $1708 \mathrm{~cm}^{-1}$, characteristic of a carbonyl group of an acid derivative; and also a broad absorption band extended from $3300 \mathrm{~cm}^{-1}$ to 2700 $\mathrm{cm}^{-1}$, which distinguishes the carboxylic acid derivatives from the rest of the carbonyl compounds. Further, absence of multiplet of an olefin proton at $\delta 5.09$, and two singlets at $\delta 1.54$ and 1.68 , characteristic of the isopropylidene structural unit of $\mathbf{3 2}$, in the ${ }^{1} \mathrm{H}$ NMR spectrum of the isolated product; which also revealed a broad singlet at $\delta 8.87$, characteristic of a carboxylic acid functionality, clearly suggested the formation of intermediate 33. This was further confirmed by it's ${ }^{13} \mathrm{C}$ NMR spectrum, which showed a quaternary carbon singlet at $\delta 179.9$ for the carbonyl group. Elemental analysis and mass spectrum finally ascertained the formation of acid 33.

After successfully synthesizing acid 33, the next job was to cyclise it to the key tetralone intermediate 31, for which 33 was treated with triflouroacetic anhydride ${ }^{14}$ in triflouroacetic acid at $0{ }^{\circ} \mathrm{C}$ for 3 hours. Under this condition, tetralone $\mathbf{3 1}$ was obtained as the sole product in $80 \%$ isolated yield as a white solid $\left(\mathrm{mp} 110^{\circ} \mathrm{C}\right)($ Scheme-8).

## Scheme-8

Reagents and conditions: a) triflouroacetic anhydride, triflouroacetic acid, $0^{\circ} \mathrm{C}, 3 \mathrm{~h}, 80 \%$.

The IR spectrum of 31 revealed absorption at $1670 \mathrm{~cm}^{-1}$, characteristic of a conjugated carbonyl group. It's ${ }^{1} \mathrm{H}$ NMR spectrum exhibited a singlet in the aromatic region at $\delta 6.63$ and a doublet $\delta 7.79(J=0.8 \mathrm{~Hz})$, assigned to the two para distributed aromatic protons. Also, ${ }^{13} \mathrm{C}$ NMR spectrum revealed four quaternary singlets at $\delta$ 124.9, 125.4, 149.2 and 162.1 ; attributed to the four aromatic quaternary carbon atoms; and one at $\delta 196.8$, attributed to the carbonyl carbon. This suggested the cyclisation of the acid side chain over aromatic ring. Also, resonance at $\delta 7.79$ in the ${ }^{1} \mathrm{H}$ NMR spectrum indicated para
directed cyclisation due to electron releasing methoxy group. Tetralone $\mathbf{3 1}$ was further confirmed by it's mass spectrum, which exhibited a peak of $(\mathrm{M}+1)^{+}$at 205 , and it was finally ascertained by it's elemental analysis, which was in good agreement with the calculated values.

Butenolide ring construction over tetralone $\mathbf{3 1}$ would have completed the synthesis of heritonin, which was achieved by utilizing the protocol developed in this group earlier. ${ }^{4}$ Accordingly, tetralone $\mathbf{3 1}$ was converted to the $\beta$, $\gamma$-unsaturated ester $\mathbf{3 4}$ by Reformatsky reaction using ethyl-2-bromopropionate, which was further dihydroxylated using osmium tetroxide in the presence of $N$-methylmorpholine- N -oxide to provide the diol $\mathbf{3 5}$ in high yields (Scheme-9).

## Scheme-9

Reagents and conditions : a) Zn, ethyl-2-bromopropionate, iodine, ether, reflux, $3 \mathrm{~h}, \mathrm{H}^{+}, 80 \%$; b) $\mathrm{OsO}_{4}(\mathrm{cat}), \mathrm{NMO}, \mathrm{CH}_{3} \mathrm{CN}-\mathrm{H}_{2} \mathrm{O}, r t, 24 \mathrm{~h}, 95 \%$.

Both the intermediates $\mathbf{3 4}$ and $\mathbf{3 5}$ were mixture of diastereomers and as the stereochemistry at these newly generated chiral centers would be destroyed at the later stages during formation of butenolide moiety, it's stereochemistry was of no consequence and hence no attempt was made to identify the diastereomers as well as their ratios. Both of these intermediates were confirmed by their IR, NMR and mass spectral data comparison with those of previously reported. ${ }^{4}$

The next task to be performed was elimination of the tertiary hydroxyl group and lactonisation to furnish butenolide ring, which was achieved using a methodology developed by this group, ${ }^{5}$ where such diols were treated with $p$-toluenesulfonic acid under
refluxing benzene for the butenolide ring construction. Following the same method, diol 35 gave a mixture of heritonin 2 and it's C-8 epimer in 3: 2 ratio, in overall $90 \%$ yield (Scheme-10).

## Scheme-10

Reagents and conditions : a) pTSA, benzene, reflux, $1 \mathrm{~h}, 90 \%$ overall.

This could be seen in the ${ }^{1} \mathrm{H}$ NMR spectrum of the product obtained after column purification, which exhibited resonances at $\delta 4.88(\mathrm{ddq}, J=12.9,4.8,1.6 \mathrm{~Hz})$ and $\delta 5.08$ (ddq, $J=13.1,4.6,1.6 \mathrm{~Hz}$ ) in 3: 2 ratio, which corresponds to the proton on the carbon bearing oxygen atom of the lactone ring, characteristic of heritonin 2 and epi-heritonin (epi-2), respectively. ${ }^{4}$ Both the isomers were separated by repeated crystallization. Pure heritonin 2 was first to be crystallized out from hot pet. ether as a white needles (mp 115$116{ }^{\circ} \mathrm{C}$ ) \{lit. $\left..^{2} 115-116{ }^{\circ} \mathrm{C}\right\}$, while epi-heritonin was crystallized from the remaining fraction using hot $10 \%$ ethyl acetate in pet. ether, as a white crystals ( $\mathrm{mp} 172-173{ }^{\circ} \mathrm{C}$ ). Both the isomers were characterized by their IR and NMR spectral data comparison with those of literature values. ${ }^{2,4}$

The IR spectrum of 2 revealed absorption at $1738 \mathrm{~cm}^{-1}$ and $1654 \mathrm{~cm}^{-1}$, characteristic of the butenolide ring structure. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2}$ exhibited the following salient features : a signal at $\delta 1.43(\mathrm{~d}, J=6.7 \mathrm{~Hz}, 3 \mathrm{H})$ was attributed to the only secondary methyl group, while the peak at $\delta 2.11(\mathrm{~d}, J=1.6 \mathrm{~Hz}, 3 \mathrm{H})$ was assigned to the methyl group attached to the butenolide ring.

Finally, heritol $\mathbf{1}$ was obtained by demethylation of $\mathbf{2}$ using anhydrous aluminium chloride in the presence of ethanethiol ${ }^{15}$ in $80 \%$ yield, without any epimerisation at C-8 (Scheme-11).

## Scheme-11

Reagents and conditions : a) $\mathrm{AlCl}_{3}, \mathrm{EtSH}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 12 \mathrm{~h}, 80 \%$.

Formation of heritol was established by it's IR and ${ }^{1} \mathrm{H}$ NMR spectral data comparison with those of literature values ${ }^{1}$ and was found to be in good agreement. Presence of an absorption frequency at $3595 \mathrm{~cm}^{-1}$, characteristic of a phenolic hydroxyl group in the IR spectrum, and absence of a three proton singlet at $\delta 3.87$ in it's ${ }^{1} \mathrm{H}$ NMR spectrum, were indicative of the attempted deprotection. Further, it's ${ }^{1} \mathrm{H}$ NMR spectrum showed only one signal, corresponds to the proton at C-8, at $\delta 4.88$ (ddq, $J=12.8,4.8,1.6$ Hz ), which indicated no epimerisation under the reaction conditions.

However, heritol thus synthesized from ( $R$ )-(+)-citronellal had specific rotation -240.5 (c 0.18, $\mathrm{CHCl}_{3}$ ), while literature reports +261.3 (concentration and solvent in which specific rotation has been taken, is not reported). Assuming chloroform as the solvent, the opposite sign of rotation indicated that the

Proposed absolute configuration of naturally isolated (+)-heritol naturally isolated (+)-heritol should have ( $S, R$ ) configuration at $\mathrm{C}-10, \mathrm{C}-8$.

Under identical reaction conditions, pure epi-heritol (epi-1) (C-8 epimer of $\mathbf{1}$ ) was obtained in $80 \%$ yield, (Scheme-11) which was characterized by it's IR and ${ }^{1} \mathrm{H}$ NMR spectral data comparison with those of reported one. It showed specific rotation +321.8 ( $c$ $0.17, \mathrm{CHCl}_{3}$ ).

### 3.5 Conclusions

Enantiopure (-)-heritol has been synthesized enantiospecifically from naturally occurring monoterpene ( $R$ )-(+)-citronellal. Absolute configuration of natural heritol has been proposed to be ( $S, R$ ) at C-10, C-8 by comparison of it's specific rotation with that of synthetically obtained one.

### 3.6 Experimental

(R)-4-(3-Methoxy-4-methylphenyl)pentanoic acid (33)

A 500 mL round bottom flask, equipped with a magnetic stir bar and 50 mL addition funnel, was charged with olefin 32 \{prepared from $(R)-(+)$-citronellal as described in chapter-2, section-2\} ( $2 \mathrm{~g}, 8.62 \mathrm{mmol}$ ) and acetone ( 20 mL ). The reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and $\mathrm{OsO}_{4}$ (cat) was added to it, which was stirred for 15 min , followed by dropwise addition of Jones' reagent $(12 \mathrm{~mL})$. The reaction mixture was stirred at room temperature for 7 h before excess of Jones' reagent was quenched by addition of isopropanol ( 5 mL ). Acetone was removed under reduced pressure, followed by dilution with water ( 50 mL ) and extraction with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $50 \mathrm{~mL} x$ 3). The combined organic layers were washed with water ( 100 mL ) and brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, $9: 1$ ) to give acid $\mathbf{3 3}(1.57 \mathrm{~g})$ as a colourless oil.

## (R)-6-Methoxy-4,7-dimethyl-3,4-dihydronaphthalen-1(2H)-one (31)

Acid $33(1.4 \mathrm{~g}, 6.31 \mathrm{mmol})$ was taken in a 25 mL round bottom flask and to this was added trifluoroacetic acid $(0.7 \mathrm{~mL})$, followed by slow addition of triflouroacetic anhydride $(1.6 \mathrm{~g}, 7.6 \mathrm{mmol})$ at $0{ }^{\circ} \mathrm{C}$, under $\mathrm{N}_{2}$ atmosphere. The reaction mixture was stirred at the same temperature for 3 h and was neutralized using saturated $\mathrm{NaHCO}_{3}$ solution ( 50 mL ), followed by extraction using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{~mL} \times 3)$. The combined organic layers were washed with brine ( 100 mL ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered and concentrated under reduced pressure. The residue was chromatographed using flash silica gel (pet. ether : EtOAc, 95 : 5) to provide tetralone $31(1.03 \mathrm{~g})$ as a white solid.

Heritonin (2) and it's C-8 epimer (epi-2) ${ }^{2,4,5}$

Diol $35(0.4 \mathrm{~g}, 1.24 \mathrm{mmol})$ was taken in a 100 mL round bottom flask, to which benzene ( 20 mL ) was added followed by catalytic amount of $p$ TSA. The reaction mixture was refluxed for 1 h , concentrated under reduced pressure and the residue was chromatographed using flash silica gel (pet. ether : EtOAc, $9: 1$ ) to provide a mixture of $\mathbf{2}$ and epi-2 in $3: 2$ ratio ( 0.29 g , overall $90 \%$ ).

Recrystallization of the solid thus obtained in boiling pet. ether furnished heritonin $\mathbf{2}$ as a white needle shaped crystals.
