

Limonoid biosynthesis in *Azadirachta indica*: Characterization of pathway genes and analysis of labeled metabolites through stable isotope feeding

Thesis Submitted to **AcSIR** For the Award of
the Degree of
DOCTOR OF PHILOSOPHY
In Biological Sciences

By
T. Aarthy
10BB12A26068

Under the guidance of
Dr. H.V.Thulasiram
CSIR-National Chemical laboratory
Pune – 411008, India
March 2019

**Everyone can rise above their
circumstances and achieve success if
they are dedicated and passionate
about what they do.**

-Nelson Mandela

CERTIFICATE

This is to certify that the work incorporated in this Ph.D. thesis entitled "**Limonoid biosynthesis in *Azadirachta indica*: Characterization of pathway genes and analysis of labeled metabolites through stable isotope feeding**" submitted by **Ms. T. Aarthi** to Academy of Scientific and Innovative Research (AcSIR) in fulfillment of the requirements for the award of the Degree of **Doctor of Philosophy in Biological Sciences**, embodies original research work under my supervision/guidance. I further certify that this work has not been submitted to any other University or Institution in part or full for the award of any degree or diploma. Research material obtained from other sources has been duly acknowledged in the thesis. Any text, illustration, table etc., used in the thesis from other sources, have been duly cited and acknowledged.

It is also certified that this work done by the student, under my supervision, is plagiarism free.

(STUDENT)

(SUPERVISOR)
Dr. H. V. Thulasiram
Principal Scientist
Division of Organic Chemistry
Pune – 411008, India

DECLARATION

I, Ms. **T. Aarthy**, hereby declare that the work incorporated in the thesis entitled “**Limonoid biosynthesis in *Azadirachta indica*: Characterization of pathway genes and analysis of labeled metabolites through stable isotope feeding**” submitted by me to the Academy of Scientific and Industrial Research (AcSIR), for the degree of **Doctor of Philosophy in Biological Sciences** has been carried out by me at CSIR-National Chemical Laboratory under the guidance of **Dr. H. V. Thulasiram**. This work is original and has not been submitted to any other university or institution for the award of any degree or diploma. Such material, as has been obtained from other sources, has been duly acknowledged.

T. Aarthy
19/3/2019

T. Aarthy
Research Fellow,
Division of Organic Chemistry,
CSIR-National Chemical Laboratory.
Pune-411008.

Dedicated to My Beloved Grandparents...

ACKNOWLEDGMENT

Feeling gratitude and not expressing it is like wrapping a present and not giving it.

- William Arthur Ward

I would take this opportunity to express my gratitude to everyone who accompanied, helped and supported me during the journey of the PhD programme.

First of all, I thank my research supervisor Dr. H. V. Thulasiram, for his constant guidance and support. I am indebted to him for introducing me to this interesting area of research. I will always cherish his valuable suggestions, which have greatly helped in developing skills and multitasking.

I am grateful to Director, CSIR-National Chemical Laboratory, Pune and Head, Division of Organic Chemistry, for infrastructure and support to complete my research work. I sincerely acknowledge the Department of Biotechnology (DBT), New Delhi for providing Junior and Senior Research Fellowships, which supported me for my research at NCL for five years.

I thank my doctoral advisory committee Chairman, Dr. Vidya Gupta, members Dr. Mahesh J. Kulkarni and Dr. Jomon Joseph for their readily suggestions, critical evaluation and reviewing of my work reports and presentations from time to time during my Ph.D.

I am grateful for the help of Dr. B. Santhakumari, Dr. Anjan Banerjee, Dr. S. Dhanasekaran, Dr. Subash chandrabose, Dr. Muthu Krishnan and Dr. Neelima Iyer during my work at NCL.

I am thankful for the timely help from Prasad, Fayaj, Sudha, which has eased my research work. I acknowledge the cheerful environment and help rendered by my labmates, Pankaj, Swati, Saikat, Prabhakar, Harshal, Dipesh, Devdutt, Krithika, Avinash, Fayaj, Shrikant, Ashish, Prasad, Sharanbasappa, Sonia, Priyadarshini, Nilofer, Ajay, Pruthviraj, Yugendra, Balaji, Radha, Uttara, Rani, Vijayashree, Ramesha, Shiva, Jennifer, Nilesh, Kuhoo, Anirban, Manoj, Ashish, Jagadeesha, Manu, Supriya, Nagesh, Varsha, Sudha, Pooja, Aaditi, Shruti, Nivedita, Chaya, Chitra, Jeevitha, Sandip, Bhagyashree, Smita, Shaila, Sneha, Nikita, Chetan, Preeti. I am happy to extend my thanks to collaborators and friends Pushpa, Bhavani, Harpreet, Arati, Soujanya, Sweta, Amar, Mahesh.

I sincerely thank friends from NCL, Swamy, Shrikant, Amrita, Swapnil, Bharat, Deepika, Bhusan, Pranali, Harshavardhan, Pankaj, HariKrishna, Jagadeesh, and IISER,

Bhavani, Nevedha, Boominathan, Suraj, Maduri, Harpreet, Vyankatesh, Amit, Kirti, Ravi, Ameya, Krithika.

I am thankful to NCL friends and colleagues Rajambal, Senthil, Sandeep, Sudha, Vinodh, Poulomi, Nimisha, Rupa, Suman, Sana, Vidya, Subhadarshinee, Harshitha, Rajeshwari, Prachi, Swetha, Reema, Rohini, Anurag, Rohil, Rahul, Meenakshi, Aswathy, Suwarna, Bhagyashree, Abha who eased the stay and work at NCL.

Friends play a major role in life by giving encouragement and happiness; I thank my college friends, Nevedha, Agatha Shiny, Geetha, Karuna, Anbu, Raji, Swathyshree, Mariayammal.

I am very happy to express my heartfelt gratitude to my family members even though, it is not enough of words for the love and affection that they showered on me. First and foremost I extend my gratitude and respect to my beloved grandparents, late Mr. M. Muthumanickam and Mrs. M. Santhadevi for their endless love, inspiration and encouragement without which I couldnot imagine how the life would have been. I thank my parents, in particular my Mom Mrs. T. Ayizhai, who ever struggled for my well being and also for her support during my Ph.D. enduring my absence since a long period. I recognize the kindness and appreciation of my dear aunty Ms. M. Athirai and I am indebted to her. I always thank Vijay for his moral support during my hardships, and reassurance during tough times. I thank all my relatives who stood together during ups and downs in course of time.

Last but foremost, I thank Almighty for blessing me with strength and good health to move ahead with enthusiasm after gaining new experience through crossing the obstacles in all the circumstances in life.

T. Aarthu

ABSTRACT

Introduction

Due to their immobile nature, plants have evolved and adapted to different environmental stresses by effective synthesis, storage and emission of secondary metabolites in the necessary time and space. These secondary metabolites or natural products are of immense fortitude to mankind due to its different kind of ameliorating property on human health ailments. Neem tree, one of the Indian medicinal plant well-known and being used for its healing property from ancient past is of profound interest and hence, the study of its biosynthetic pathway, understanding its localization, regulation etc., will pave the way to design an efficient way of treating human diseases as a natural means of medicament. The thesis entitled, “**Limonoid biosynthesis in *Azadirachta indica*: Characterization of pathway genes and analysis of labeled metabolites through stable isotope feeding**” is concerned with the study of biosynthesis of limonoids and other secondary metabolites and their localization in neem.

CHAPTER 1

Introduction and objective of the thesis

Neem tree is known for its bountiful and diverse natural products conferring numerous medicinal and agricultural uses for mankind¹. Among these plenty of natural products, most of them belong to triterpenoid (limonoids)². More than 150 limonoids have been isolated and characterized from neem so far and each of them has been studied for its biological activities³. Azadirachtin, one of the highly complex limonoid had been studied widely for its excellent anti-feedant, insecticidal property, with no proven harmful effects on vertebrates and are found to be an unsurpassable natural product identified hitherto for its efficiency. The successful chemical synthesis of this complex molecule was accomplished after 22 years of efforts by Ley *et al.*^{4, 5}. Azadirachtin and other bioactive limonoids are highest in the fruits of neem tree. There is an indispensable requisite for metabolic engineering of this pathway in heterologous system. Therefore, the study of azadirachtin biosynthetic pathway is highly essential to harness the biosynthetic capacity of the tree for its medicinal properties. Following are the main goals of the thesis,

- To identify and characterize the organelles/ intra-cellular compartments involved in the storage of limonoids in different tissues.
- To trace the flow of carbon in limonoid skeleton through stable isotope feeding experiments.
- To study the expression level of the genes involved in isoprene biosynthetic pathway and to characterize the putative candidate genes associated with limonoid biosynthesis.

CHAPTER 2

Development of *in vitro* cultures of neem, limonoid profiling and study of organelles and cells involved in limonoid storage

In our laboratory, we have identified previously, the tissue and developmental stage specific differential distribution and abundance of ring intact (basic) and C-seco limonoids in different neem tissues⁶. This incredible and impressive abundance of limonoids in fruit and leaf tissues actuated us to look for the specialized cells involved in accumulating limonoids and also the development of neem plantlets, *in vitro* callus from kernel and callus derived suspension system to study limonoid biosynthesis. C-seco limonoid group exists as major limonoid synthesized in the *in vitro* plantlets and also callus and suspension cells. In the present study, histochemical analysis of different tissues has been carried out to study the limonoid localization in cellular and subcellular compartments. It suggested that laticifers are rich in basic limonoids and oil bodies are found to be the major source of C-seco-limonoids in pericarp and kernel of neem fruit respectively, whereas limonoids exist in abundance in idioblast vacuoles in pericarp and leaf tissues. Average number of idioblasts per mm² of tissue was comparatively high in pericarp to that of leaf, which matched with the abundance of limonoids in these tissues respectively (Figure 1).

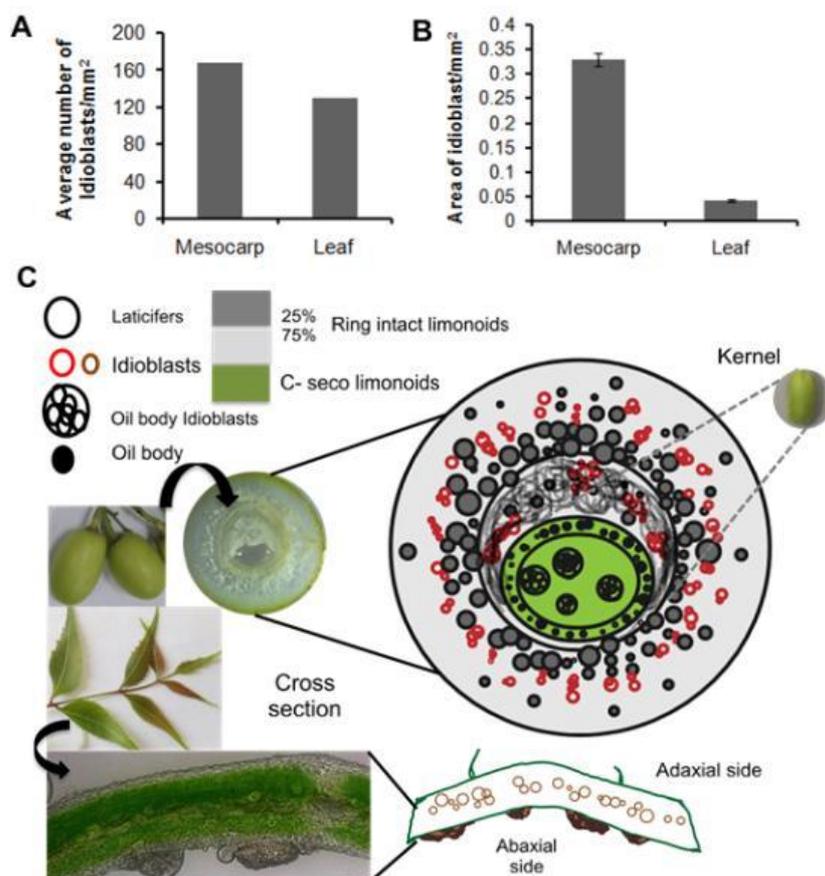

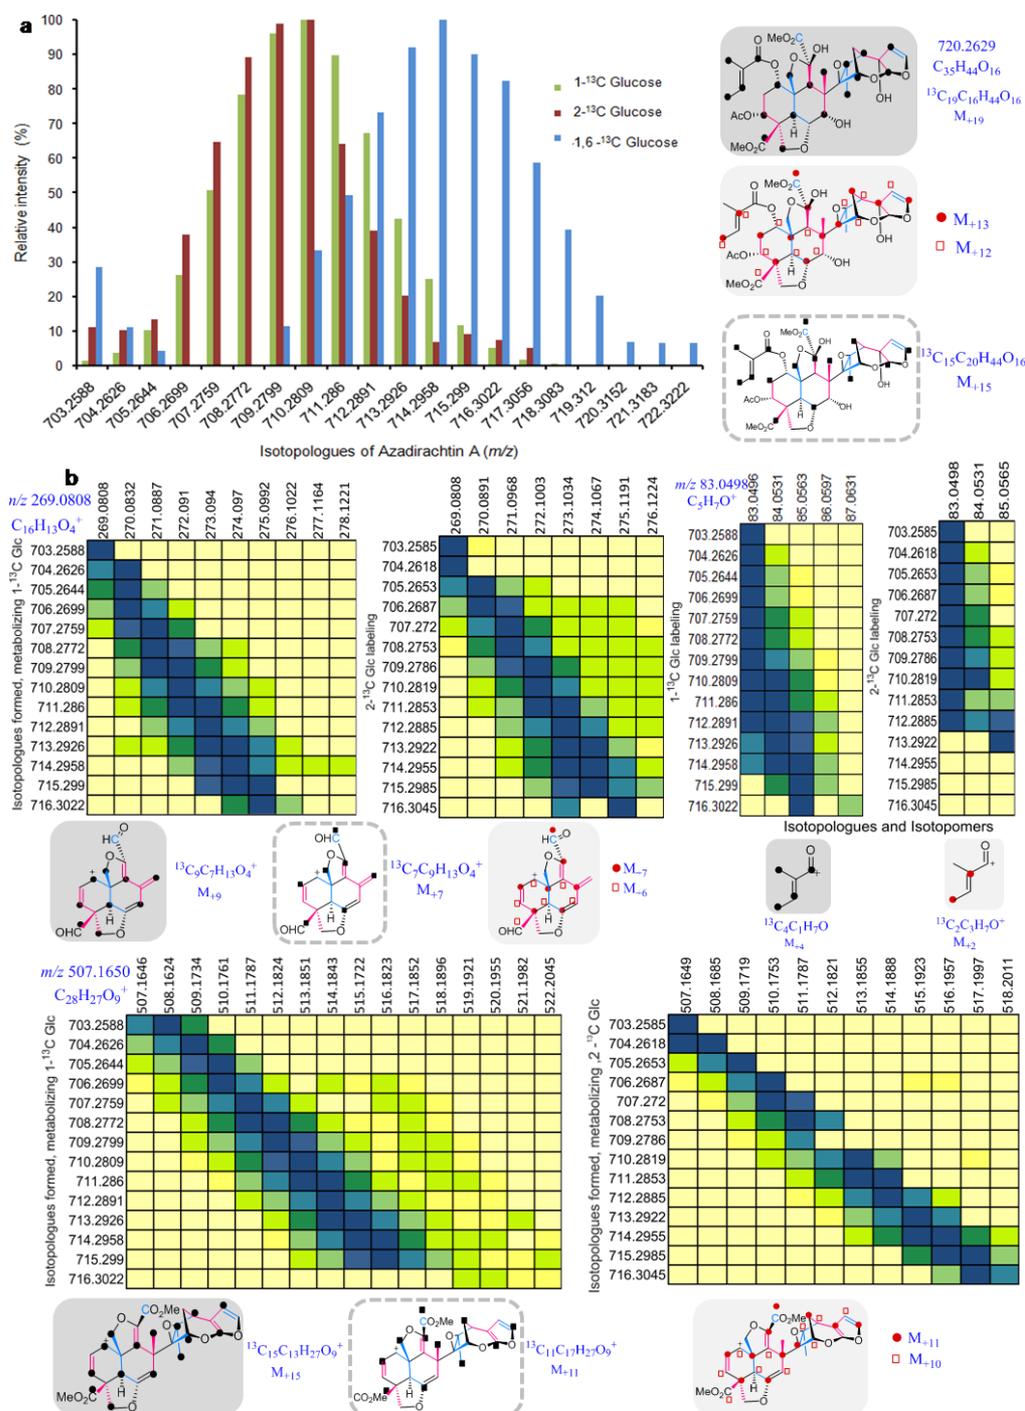

Figure 1. (A) Number of idioblasts in different tissues and (B) their area contribution (C) Model showing cellular and subcellular compartmentalization of limonoids in neem fruit and leaf

CHAPTER 3

Ex vivo* tracer study of limonoid biosynthesis in *Azadirachta indica

Neem tree serves as a cornucopia for triterpenoids called limonoids that are of profound interest to humans due to their diverse biological activities. A well-known potent anti-feedant, highly complex molecule, azadirachtin and many other biologically active limonoids are distributed in different tissues of neem⁷. The biosynthetic machinery that plant cell employs for the production remains unexplored for this wonder tree. Herein, we report the tracing of limonoid biosynthetic pathway through feeding experiments using ¹³C labeled isotopologues of glucose in neem cell suspension. In order to identify the signature fragment of azadirachtin A generated through ESI-MS, fragments generated from MS/MS of azadirachtin derivatives such as azadirachtin B, H, 3-deacetylazadirachtin A, epi-azadirachtin D, vepaol were studied comparatively at different normalized collision energies. The plausible fragmentation pathway for azadirachtin A has been proposed showing the structure-fragment relationship. This helped in tandem mass spectrometry (MS/MS) analyses of labeled limonoid

extract, which lead to the identification of signature isoprenoid units involved in azadirachtin and other limonoid biosynthesis (Figure 2). Therefore, the isoprene units contributed for limonoid skeleton biosynthesis are found to be formed through mevalonate (MVA) pathway (Figure 3).

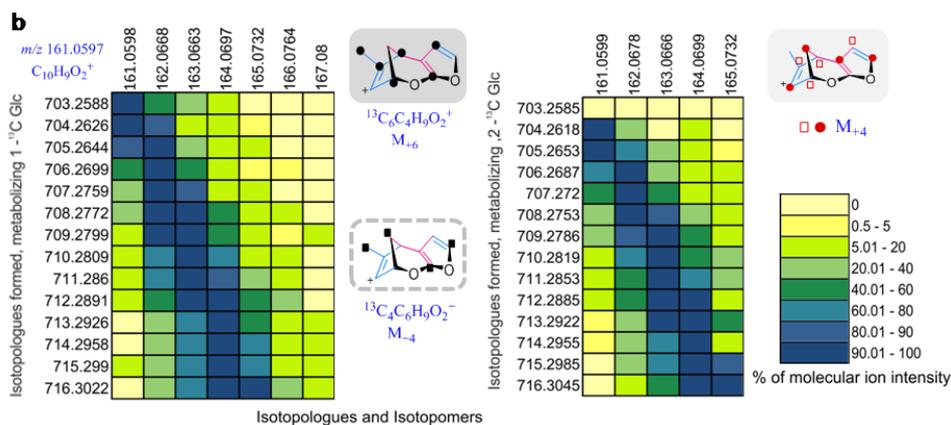

Figure 2. Distribution of azadirachtin A isotopologues and isotopomers obtained from ESI-MS and MS/MS analysis. (a) Comparison of relative intensity of isotopologues of protonated ion adduct $[M-H_2O+H]^+$ of azadirachtin A obtained from independent labeling experiments with $[1-^{13}C]$, $[2-^{13}C]$, $[1,6-^{13}C]$ Glc. (b) Heatmap of isotopologue of azadirachtin A in the mass spectra vs. relative intensity of each of the isotopologues for individual fragments (m/z 83.0498, 161.0597, 269.0808, 507.1650 derived from different part of the skeleton are represented) obtained when subjected to tandem MS at collision energy of 20%. The structure of the molecule and its fragments are given in grey boxes for the molecule denoting its ^{13}C pattern of formation through MVA pathway and dashed line boxes for its formation through MEP pathway. The black dots and squares represent the position of ^{13}C carbon incorporated from $[1-^{13}C]$ Glc / $[1,6-^{13}C]$ Glc whereas the red dots corresponding to those from $[2-^{13}C]$ Glc.

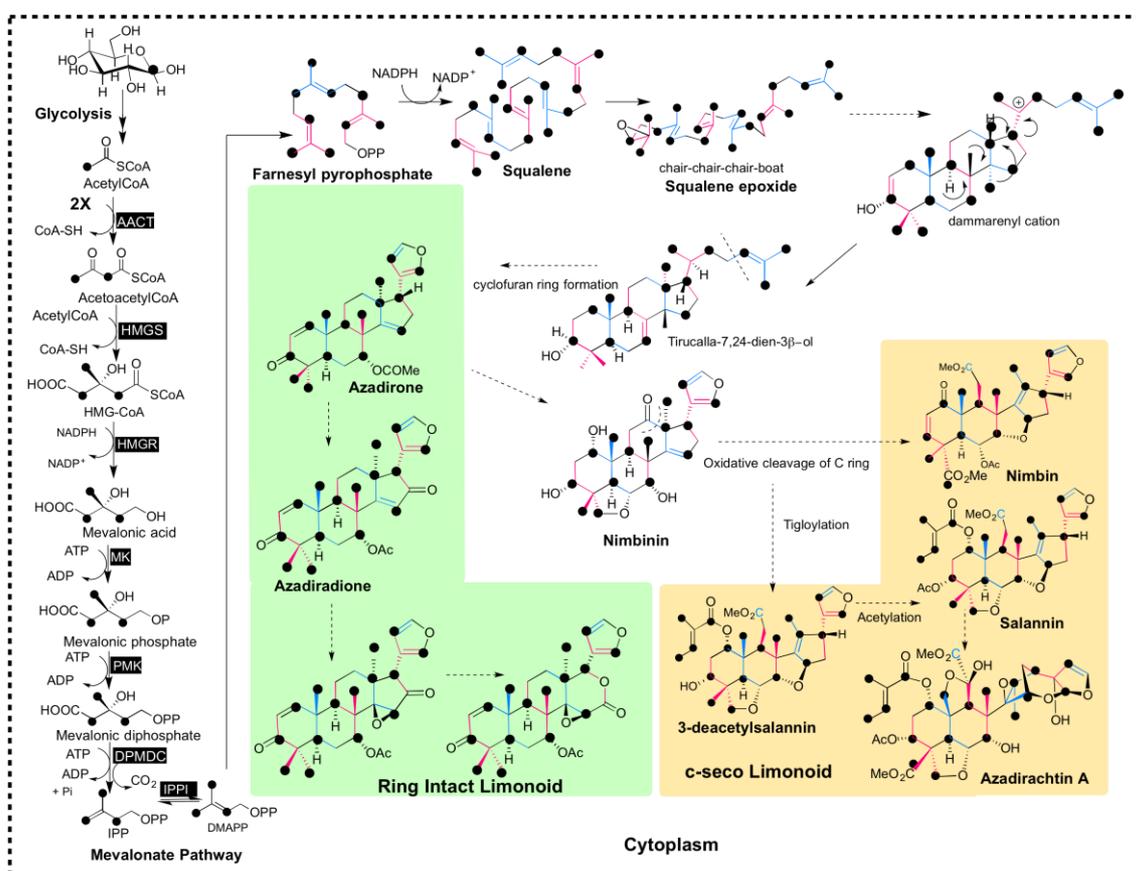

Figure 3. Simplified scheme showing limonoid biosynthesis in neem being contributed by isoprene units formed through MVA pathways evident from the labeling experiment with ^{13}C glucose. C-seco and ring intact limonoid are represented in yellow and green boxes respectively. (Alternate isoprene units of the limonoid skeleton are shown in pink and blue, dotted arrow shown here are the uncharacterized steps in the pathway).

CHAPTER 4

Study of the role of MVA and MEP pathway in limonoid biosynthesis and characterization of pathway genes

To study the role of MVA and MEP pathway towards limonoid biosynthesis, chemical inhibition of the pathways along with concomitant ^{13}C Glc labeling was carried out. Treatment of cell suspension with mevinolin, a specific inhibitor for MVA pathway, resulted in drastic decrease in limonoid levels whereas their biosynthesis was unaffected with fosmidomycin mediated plastidial methylerythritol 4-phosphate (MEP) pathway inhibition (Figure 4). This was also conspicuous, as the expression level of genes encoding for the rate-limiting enzyme of MVA pathway, 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase (HMGR) was comparatively higher to that of deoxyxylulose-phosphate synthase (DXS) of MEP pathway in different tissues and also in the *in vitro* grown cells as evident from real-time PCR analysis (Figure 5).

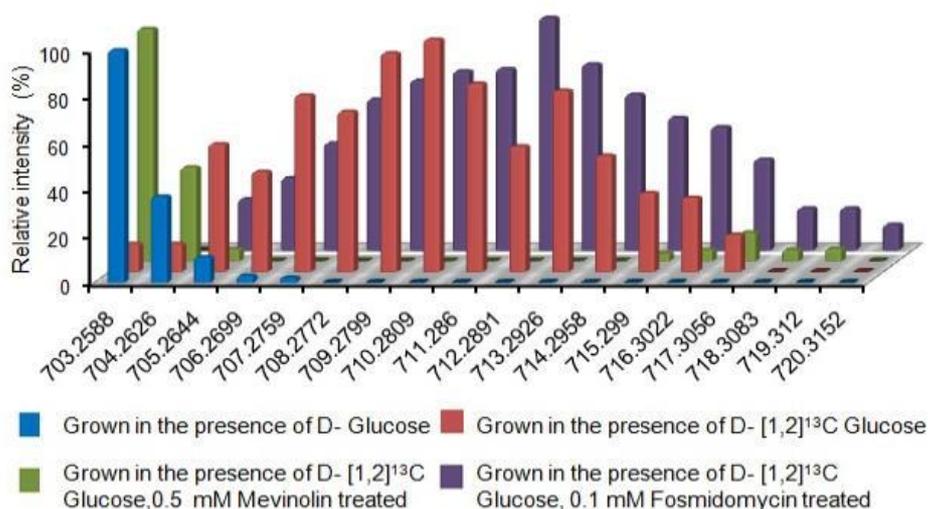

Figure 4. Chemically inhibited MVA and MEP pathway cells grown in the presence of $[1,2-^{13}\text{C}]$ Glc to monitor the formation of isotopologues. Fosmidomycin treatment didn't interfere with (limonoid) azadirachtin A biosynthesis as evidenced from the labeling experiment carried out during the pharmacological inhibition of the cells with mevinolin and fosmidomycin.

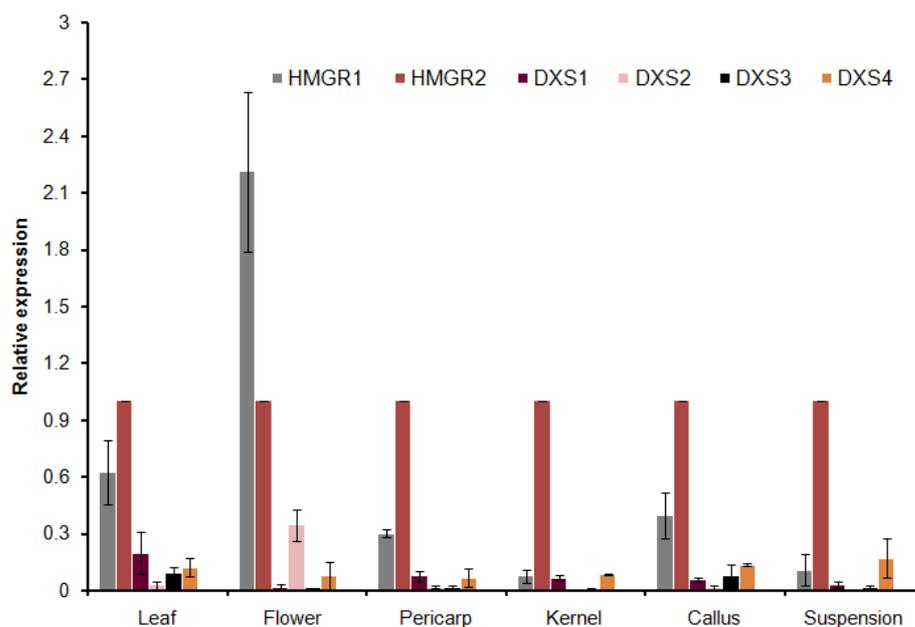

Figure 5. Expression profile of HMGR and DXS genes in various tissues relative to the expression of HMGR2.

This chapter also deals with the cloning of putative acyltransferase genes in neem. Neem limonoids being triterpenoids are biosynthesized from the triterpene intermediate squalene, which en route to 2,3 oxidosqualene leading to cyclized triterpene intermediate which further modifies to form protolimonoids. Limonoids further undergoes numerous functionalizations such as redox reactions, hydroxylation, acetylation, tigloylation etc. to form several limonoids in multistep pathway, which are yet to be elucidated. In order to understand limonoid diversity in neem, putative acyltransferase ORFs were selected from neem transcriptome for cloning. The selected acyltransferases matched with BAHD family of plant acetyltransferases, which transfers group from CoA to natural products. The two full-length ORFs were cloned into bacterial and yeast vector systems and characterization of the expressed protein to understand its function with limonoids and/ other terpene or non-terpene alcohols as substrates.

Chapter 1

Introduction

1.1. Introduction

In living system, chemical reactions occur through careful regulation of integrated network of enzymes existing in the form of metabolic pathways. The processes involved in the synthesis and transformation of crucially important molecules of life such as carbohydrates, proteins, fats and nucleic acids are the primary metabolic processes and the molecules formed are termed as primary metabolites¹. In contrast, other groups of metabolites are restricted to a specific organism or group of organism or produced under specific conditions, specific location or time, and such compounds are called as secondary metabolites¹. They are broadly classified into three major groups as terpenoids, alkaloids and phenylpropanoids^{1,2}.

These secondary metabolites play a vital role in the protection of the organism such as deterrence or avoidance of the predators through toxic compounds, production of volatiles and coloring agents serving to attract or interact with other organisms³. Plants due to its sessile nature need to survive extraordinary stresses which can be carried out using ideal mechanism mediated through secondary metabolites^{1,3}. Hence, they produce diverse number of natural products in order to survive in case of biotic and abiotic stresses occurring from the environment². These molecules may directly be involved in defense or in the chemical signaling to activate different pathways to positively or negatively interact with the organism in the environment. Such metabolites formed as a result of secondary metabolism also serves as pharmacologically active natural products. Thus, the natural products produced by microorganisms, plants and marine species have been successfully employed as a drug candidate for treating human ailments. These natural products serve as lead molecules for drug discovery. To exemplify, aspirin and taxol derived from willow and yew tree serves as a medication for fever and cancer chemotherapy respectively, and are of great pharmacological significance for mankind. The scientific plant secondary metabolite research can be dated to 1805, marked by the isolation of morphine from poppy (then called as *Principium somniferum*) by a German pharmacist, Wilhelm Sertürner⁴. Since that time, research in this field has been developed in three aspects as

1. Mechanical insights into biosynthetic pathway.
2. Functional role of them as a communication, protection, attraction and defense responses to the producer with other organisms.

3. The third aspect as the evolutionary connection between gene diversity and plasticity of secondary metabolites playing an ecological role in dynamic interactions of plant with its varying environment^{4,5,6,7}.

Knowledge on mechanistic aspects of metabolites advented with radioactively-labeled nuclides in early 1950s followed by the emergence of stable nuclides as tracers^{4,5,6,7,8}. Ecological aspect has been realised post-1950s based on understanding such as gene duplication, one of the major driving forces for gene diversification resulting in metabolite diversity^{4,5,9,10}.

Hence, depending on the significance of natural product for mankind, the secondary metabolite biosynthetic pathway has been intensively studied in plants. An example of plant with numerous bioactive molecules studied for its various pharmacological activities is the medicinal tree *Azadirachta indica*.

1.2. Neem tree – *Azadirachta indica*

In 1830, French botanist, Antoine Laurent de Jussieu identified *Melia Azadirachta*, which he renamed later as *Azadirachta indica* A. Juss. The Latinized form of the name is derived from Persian as *Azadi*- free, *diracht*- tree, which means, the tree free from insect and diseases¹¹. Neem tree, gained honour as a wonder tree, native to Indian sub-continent is one of the highest source of secondary metabolites. It has been used traditionally since ancient times in Ayurveda, Siddha and Unani medicine for the treatment of myriads of human ailments and is slowly drawing the attention of scientific community because of its immense, inexpensive and multifaceted medicinal potential^{11,12}. Every part of the tree has been studied by various research groups all over the world for its chemical composition and has been completely characterized. The major metabolic diversity of neem has been attributed to limonoids, exclusively found in Meliaceae family of trees belongs to the terpenoid class of metabolites¹³. Apart from these triterpenes, various other terpenes such as monoterpenes, sesquiterpenes and diterpenes are found to be present in neem¹⁴. Other class of secondary metabolites such as phenolics, flavonoids, chalcones and coumarins has also been characterized from neem^{14,15}. Such a diverse secondary metabolite biosynthesis has evolved in the plant for its defense from the environmental and biotic factors, and this has been a boon to mankind as it serves as medicinal natural products for treatment of various ailments.

Apart from these diverse natural products, it is a rich source of fatty acids and aliphatic hydrocarbons. Fatty acids of neem comprise triglycerides (TAG) of oleic, palmitic, stearic acids. Plenty of knowledge has been accumulated over the years about the plethora of medicinal properties of this tree ^{16,15,17}.

Figure 1.1. A healthy neem tree in the CSIR-NCL campus used in this study.

The tree has been placed in the following systematic position.

Kingdom: Plantae
(unranked): Angiosperms
(unranked): Eudicots
(unranked): Rosids
Order: Sapindales
Family: Meliaceae
Genus: *Azadirachta*
Species: *A. indica*

1.3. Ethnobotany and ethnomedicine of neem

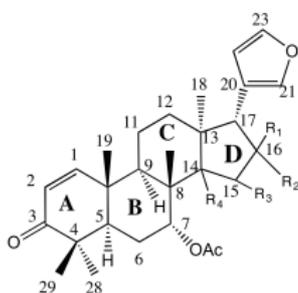

Neem has been used in the folkloric and traditional system of medicine in different parts of south-Asian continent¹¹. Neem seed has become integral part of farming in Indian agricultural system due to its insect derogating property¹⁸. Leaves and twigs are used as manure and mulched in the agricultural fields. Fresh and young twigs are used by people to keep the teeth clean, neem leaves or oil is burned to keep away the mosquitoes, leaves soaked water, is used for treating skin ailments and chicken pox etc.¹⁹. Therefore, neem twigs and leaves are used to treat dental and gastrointestinal disorders, malaria fevers, skin diseases in folklore medicine in India^{20,18,12}. Whereas in Bali (Indonesia), the neem leaves are used as a diuretic and to treat diabetes, headache, heartburn, and also for stimulating appetite¹². The plethora of medicinal properties of the tree is attributed to several class of bioactive natural products, the predominant ones are the triterpenes called limonoids¹³.

1.4. Limonoids

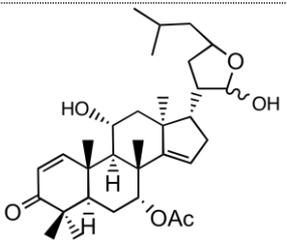

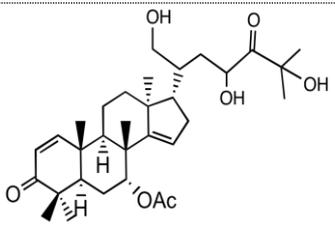

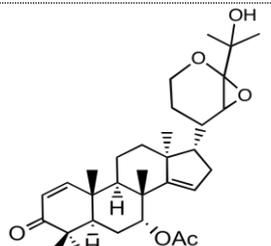

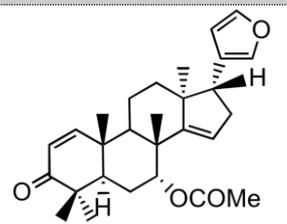

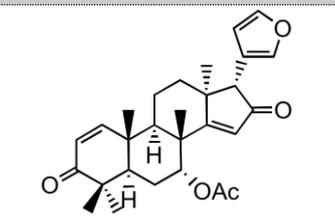

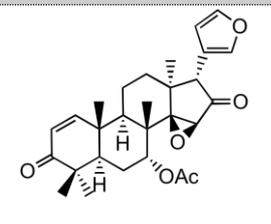

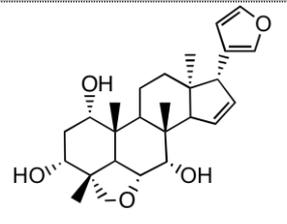

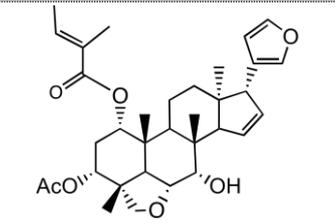

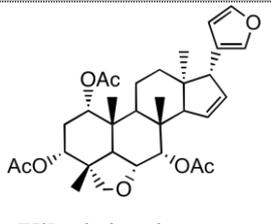

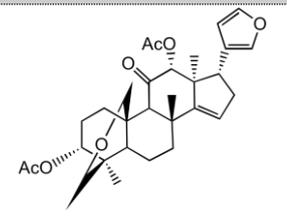

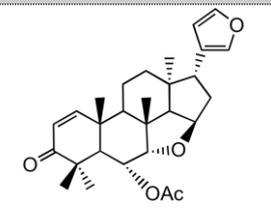

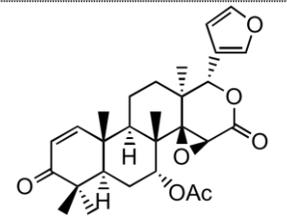

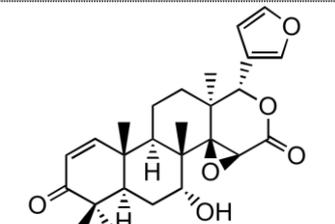

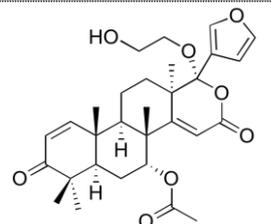

Limonoids are present and widely distributed in the families of Meliaceae, Rutaceae and in few species of Simaroubaceae¹³. The term limonoid was coined after limonin from citrus, the first isolated bitter tasting principle²¹. Limonoids from neem are termed as meliacins²¹. Based on their chemical, they are termed as tetranortriterpenoids. They all possess 4,4,8-trimethyl-17-furanylsteroid skeleton or a metabolite derived from the skeleton. They are of moderate polarity, insoluble in water but soluble in organic solvents. Limonoids are bioactive molecules that have undergone complex functionization in the skeletal structure composed of steroid skeleton consisting of A, B, C and D rings¹³. The C ring is cleaved and opened to give a group of limonoids called C-seco limonoids and the ones without such modification are termed as ring intact (basic) limonoids. Based on the modification in the ring, limonoids are further classified into six different groups such as promeliacins, amoorstatins and vepinins, vilasinins, azadirones, gedunins, and c-seco meliacins such as nimbins, salannins, azadirachtins^{14,21,16,2,4}.

Protolimonoids or protomeliacins contain C-8 side chain at C-17 position and are the precursor for all the limonoids¹⁴. Azadirone group of limonoids are predicted to be the next intermediate after protolimonoids and first tetranortriterpenoids formed from protolimonoids¹⁴. Vepinins are molecules, which has an oxygen bridge between C-7 and

C-15 positions whereas, vilasinins possess ester linkage between C-6 and C-28 positions¹⁴. Amoorstatin is the only group of limonoid which possess oxygen bridge between C-9 and C-29 position, however it neither has any ether linkage between C-6 and C-28, C-7 and C-15 nor C-14 and C-15 like that of other groups of limonoids¹⁴. Gedunin possess epoxy lactone in the D ring due to insertion of oxygen between C-16 and C-17¹⁴. C-seco limonoids are characterized by opening of C ring and ether bridge formation at C-7 α and 15 β positions as found in nimbolide, nimbin, salannin and its derivatives¹⁴ (Figure 1.2).

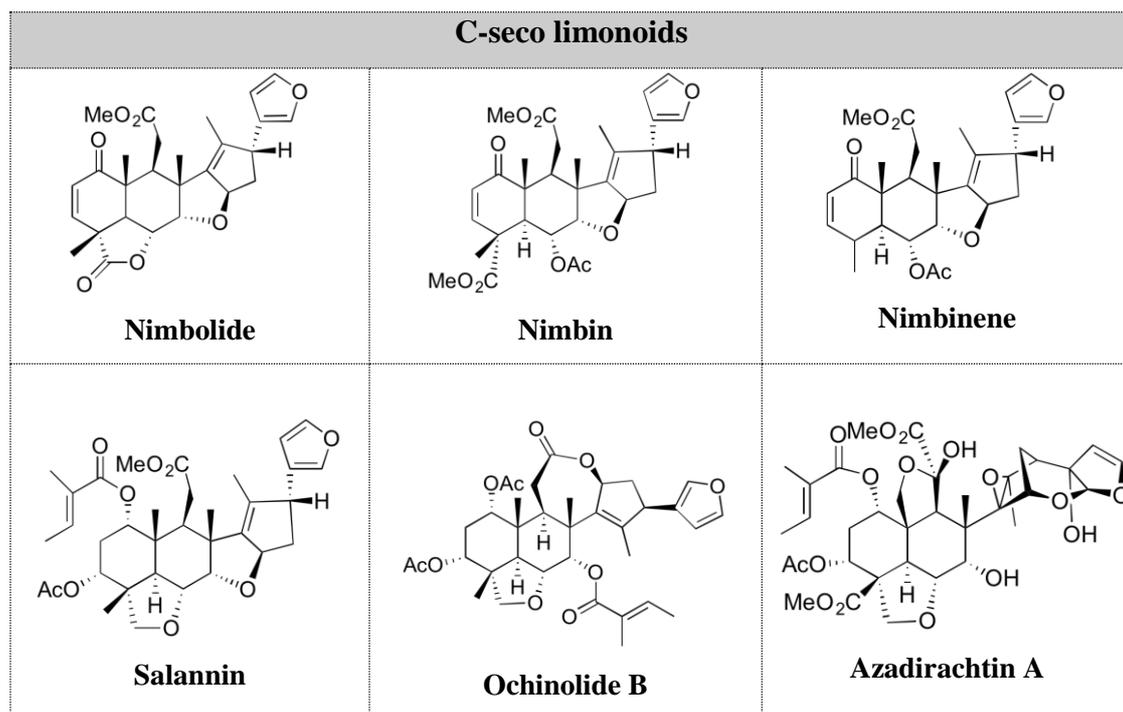

Figure 1.2. Skeletal diversity of neem limonoids. Chemical structures of limonoids identified in this study classified according to ring modification, as ring intact and ring C- seco limonoids.

1.5. Isolation of neem limonoids

Neem limonoid isolation has been successfully employed for more than six decades, indeed, with greatly evolving separation technologies thereby expediting and simplifying the purification of individual limonoids. Siddiqui was a pioneer in the field of limonoid isolation from neem tree²². The first limonoid isolated by him was nimbin in the year 1942¹⁴ and followed by many other limonoids^{14,15,23–26}. Most fascinating limonoid, azadirachtin A possessing potent anti-feedant and exhibiting growth regulatory activity against insects was first isolated by Morgan in 1968²⁷. Before the isolation of azadirachtin A, in the year of 1959, the extra-ordinary anti-insecticidal property of neem tree was already recognized by Heinrich Schmutterer, when he observed that the desert locust, *Schistocerca gregaria* didn't affect the neem tree during the invasion of other plants in Sudan²⁷.

Since limonoids are present as complex mixture, they cannot be isolated and quantified directly from the crude extract, but requires fractionation in case of isolation from larger quantity sample. Flash chromatography is a rapid technique employed for the separation of limonoids in fractions from the complex mixture of neem metabolite extract which contains tremendous amounts of green pigments^{28–30}. Biotage™ flash

chromatography developed has been an improved and quicker method when compared to the usage of gravity column chromatography²⁹. Supercritical fluid chromatography has also been successfully employed for the analysis of limonoids in the smaller scale^{29,31}. Counter-current chromatography (CCC), a liquid-liquid partition method has been successfully used for the separation of different limonoids in fractions prior to HPLC, as it helps in avoiding irreversible contamination of solid support matrix due to pigments, unlike other techniques³². Combined used of preparative layer chromatography, open-column reversed phase chromatography and HPLC were instrumental in the isolation and purification of azadirachtins and other major limonoids to its highest purity for different studies^{30,33–36,37–40,41,31,42}. The pure azadirachtin congeners were isolated efficiently using reverse phase medium-pressure liquid chromatography (MPLC). Saikat *et al* has developed a MPLC based separation method for expedient isolation of various limonoids in fractions from crude extract of neem in large scale^{43,44}. Liquid Chromatography Electrospray Ionization Tandem Mass Spectrometry and atmospheric pressure chemical ionization provided the rapid, sensitive and accurate quantification of limonoids^{45,46}. More than 150 limonoids have been isolated and characterized from neem so far and fascinating biological activity of some of them has been extensively studied^{13,21}.

1.6. Bioactivity of neem limonoids

The bioactive potential of neem limonoids has been realized in the fields of agriculture and human welfare.

1.6.1. Neem limonoids in Agriculture

Azadirachtin A, an effective insect growth deterrent, is found to be the best potential natural insecticide candidate identified so far from the plant sources²². It also possesses remarkable non-toxicity to vertebrates^{22,47}. Unlike other insecticide, which exerts its effect on the nervous system of insects, azadirachtin was known to act on the endocrine system⁴⁸, thereby affecting the feeding behavior, development, reproduction and metabolism in insects. Its effect on ecdysteroid and juvenile hormone titers of insect is through blockage of morphogenetic peptide hormone release (e.g. PTH; allatotropins)⁴⁷. Hence, the physiology of the insect is affected resulting in overall reduction in fitness of the insect⁴⁷. EC_{50} vary from 10^{-10} to 10^{-9} M and 10^{-5} to 10^{-3} M for

insect and mammalian cell lines respectively, and hence toxicity of it is 100 times less on mammals²². Thus, azadirachtin act as an ecdysis inhibitor, growth inhibition occurs through hormonal imbalance, and acts as an anti-feedant by the stimulation of specific deterrent chemoreceptors, interfering with other chemoreceptors on the mouthparts⁴⁸. It also interferes with the pupation and adult eclosion rates⁴⁹. Azadirachtin A was found to possess acaricidal activity as evidence from the activity against the camel tick, *Hyalomma dromedarii*⁵⁰. Azadirachtin A, B and H were found to possess nematicidal activity as shown from the study of their activity against the reniform nematode *Rotylenchulus reniformis* at EC₅₀ of 119.1 ppm, 96.6 ppm and 141.2 ppm respectively^{24,51}. Apart from the potent insecticidal limonoid azadirachtin A, limonoids such as salannin, 7-deacetylgedunin, gedunin, 17-hydroxyazadiradione, and 6-deacetylnimbin are also found to affect the gut enzyme activity and glycolytic enzyme lactate dehydrogenase (LDH) on rice leaf folder larvae thereby providing a evidence that gut physiology of larvae and ⁵² are disturbed by the uptake of limonoids⁵³. 6 β -hydroxygedunin inhibited 50% of the growth of *Helicoverpa armigera* and *Spodoptera litura* with higher efficacy in comparison to gedunin, salannin, azadiradione, nimboicinol and nimbinene⁵⁴⁻⁵⁶.

Margosan-O[®] a commercial product made of neem extract concentrate was approved by USA Environmental Protection Agency for use as a natural pesticide which was followed by the availability of several neem-based products from different countries⁵⁷. The commercial product Margosan-O[®], contains the potent anti-feedant azadirachtin and it fulfills all the criteria of effective insect anti-feedant which includes the need for selective toxicity, activity at low concentration, economic viability, stability, and compatibility with existing plant protection methods⁵⁸. Neem oil, a major component extracted from neem kernel is found to increase the efficacy of neem based insecticides⁵⁹. It also helps in the reduction of virus transmission by aphid, when compared to oil-free extracts^{49,60-65}. Neem oil is also found to be potential pesticide for termite control⁶⁶ and has strong acaricidal activity^{67,50,68,69,70,71,72,73,74}. Formulations of neem oil was also found to be a effective fungicide as seen from the studies on the pathogenic fungus *Macrophomina phaseolina* and *Sclerotium rolfsii*⁷⁵. The oil also showed activity against the larvae of malarial vector mosquitoes^{76,73,77}. Toxicity of neem oil has been very well documented for various agricultural pests across its all

developmental stages from nymph, larvae to adult insects^{72,78,79,80,81,82,83,84,85,86,87,88,89,90,91,92}.

1.6.2. Neem limonoids in Pharmaceutical and human welfare

Different parts of neem tree have been employed for the treatment of human ailments from time immemorial in traditional system of medicine in India. Neem extracts from various parts of the tree have been proved to have the following properties such as anti-malarial, anti-microbial, anti-inflammatory, anti-pyretic, anti-mitotic, anti-tubercular, anti-viral, anti-fertility, anti-diabetic, anti-gastric ulcer, anti-arthritic, anti-carcinogenic etc. through various *in vitro* and *in vivo* studies²¹. But, few studies projects the role of individual limonoids which confer the therapeutic value for respective extracts, its mechanism of action, its effect on other pathways in the cell, dosage level etc. Neem bark extract showed activity against Herpes simplex virus type-1, the causative agent for various skin lesions to encephalitis. A ring intact limonoid, mahmoodin showed significant anti-bacterial activity against various Gram-positive and Gram-negative organisms²⁵. The anti-angiogenic potential of ethanol extract of neem leaves over human umbilical vein endothelial cells has been evaluated by Mahapatra *et al.* and the study showed that limonoids such as nimbolide and 2,3-dehydrosalannol effects it through inhibition of vascular endothelial growth factor⁵².

Nimbolide, a limonoid from leaf and flower, arrested the growth of murine neuroblastomas cells⁹³ and human carcinoma cells (HT-29), through the upregulation of p21, which is the downstream effector of p53, a gene that encodes anti-cancer protein¹⁹. A recent study provided mechanistic insights into therapeutic potential of nimbolide, as it promotes apoptosis and attenuates cell proliferation in carcinomas⁹⁴. Anti-proliferative, apoptosis inducing effect and mechanism of action of nimbolide has been elucidated and described by Singh *et al.* in prostate cancer cell lines⁹⁵. Another individual group has studied its therapeutic potential for pancreatic cancer as it regulates apoptosis and autophagy in pancreatic cancer cells⁹⁶. Neem limonoids induces intrinsic p53-independent apoptotic cell death in multiple cancer cell types⁹⁷. The manifestation of anti-cancer activity by gedunin was found through inhibition of heat shock protein (hsp90) in breast cancer cell lines⁹⁸. In addition to the apoptotic potential of gedunin, it is effective in causing erythrosis, the suicidal death of erythrocyte which is characterized by cell shrinkage⁹⁹. Gedunin's antimalarial activity was studied to be efficient against

Plasmodium falciparum when compared to the anti-malarial drug chloroquine itself as per a study made by MacKinnon *et al*¹⁰⁰. *In vitro* anti-plasmodial activity was exhibited by the limonoids, neemfruitin A and B isolated from neem fruit, in addition gedunin and azadirone, the limonoids already known for this activity¹⁰¹. Protective effect of salannin on gastric lesions and spermicidal effect of salannin, nimbin and nimbidin has been identified. Nimbidin, a mixture of tetranortriterpenes such as nimbin, nimbinin, nimbidinin, nimbolide and nimbidic acid also possesses potent anti-inflammatory, anti-arthritic and anti-ulcer activities as evidenced by the study which showed the inhibition of some of the functions of macrophages and neutrophils relevant to the inflammatory response by the action of nimbidin *in vitro* and *in vivo* in rats¹⁰². Macrophage migration inhibitory factor (MIF) responsible for proinflammatory reactions in many infectious and non-infectious diseases is inhibited by epoxyazadiradione, the mechanism of action of it is through inhibition of tautomerase activity of MIF¹⁰³. Azadiradione and gedunin could bind and inactivate Human pancreatic α -amylase (HPA) inhibitors thereby rendering it to be used for the further studies towards the development of anti-diabetic drug¹⁰⁴. Azadirachtin A, apart from its agronomical potential was found to have an osteogenic activity as it stimulated osteoblast differentiation and mineralization of bones in an *in vivo* study carried out in pups¹⁰⁵.

Azadirachtin possess inhibitory action against Rice Bran Lipase (RBL) which can be used for the increased shelf life of food, as lipase activity yields high levels of free fatty acids in the oil, which becomes unsuitable for processing to edible oil¹⁰⁶.

1.7. Neem limonoid - Terpenoids

Limonoids belong to the terpenoid class, one of the largest classes of natural products. The term 'terpene' is derived from the Greek name for terebinth tree, *Pistachia terebinthus*, the source of turpentine¹⁰⁷ and the resin of it containing terpenes is used by people all over the Middle East for treatment of various diseases. Terpenoid (Isoprenoids) constitute diverse organic compounds, which plays major biological role in all the three domains of life (bacteria, archaea and eukaryotes). More than ten thousands of the discovered terpenoids, are produced by plants¹⁰⁸. Such a huge structural diversity of enormous number of isoprenoids is contributed by C₅ carbon skeletons of isoprene units, the number of repetitions of this unit, cyclization, rearrangement and various further chemical modifications¹⁰⁹. Almost all the metabolic processes involved

in the cell require isoprenoids, and isoprenoids exist as either containing only of isoprene units or a part of molecule composed of isoprene unit. They are again classified into primary and secondary metabolites based on their functional significance in the cell¹⁰⁹. As primary metabolites, sterols give structural integrity to the cell membrane in most eukaryotes and it is replaced by hopanoids in prokaryotes^{109,110}. In vertebrates, sterols act as precursors for steroid hormones and bile acids. Further, plant growth regulators such as abscissic acid, gibberellic acids and brassinosteroids mediate many physiological responses by inducing diversity of responses in plants; photosynthetic pigments such as carotenoids, chlorophylls are involved in carbon fixation in all the phototrophs¹¹¹. Long acyclic isoprenic chains in the quinones such as plastoquinone-9, plastoquinone K1, ubiquinone, menaquinone, tocopherol, dolichols are produced as primary metabolites through 'Isoprenoid pathway'^{109,110}. Ubiquinones and menaquinones are electron carriers and the major components of the aerobic and anaerobic respiratory chains, respectively¹⁰⁹. Dolichols are long-chain, membrane-bound isoprenoids, which are required for cell wall peptidoglycan synthesis¹⁰⁹. Prenylated proteins are involved in the regulation and sub-cellular molecule trafficking. Plants produce myriads of secondary metabolites that mediate important interactions between plants and their environment¹⁰⁹. And most of them are defense compounds and they are of boon to mankind as it finds application in medicine and agriculture. They are conveniently classified into monoterpenes, sesquiterpenes, diterpenes, sesterpenes, triterpenes, tetraterpenes, and polyterpenes based on the number of basic isoprene unit it contains¹⁰⁹.

1.8. Chemistry of limonoids

The major group of isoprenoids present in neem is triterpenoids, which can be classified as proto-limonoids, mononortriperpenoids, di-, tri-, tetra-, penta-, hexa- and nona-nortriperpenoids depending on the number of carbon units removed from the proto-limonoids during its formation^{14,21}. Limonoids fall in the category of tetranortriperpenoids, which is formed by the excision of terminal four carbon units during its formation from the proto-limonoids¹¹².

Protolimonoids are suggested to be initial step or immediate limonoid intermediates formed in the biosynthetic pathway¹⁴. They have an intact C-8 side chain present on the C-17 of the D ring. Further modification occurs in the side chain for the

formation of furan ring, attached to C-17 of D ring. The protolimonoids so far identified and isolated from neem include meliantriol, melianone, nimolinone, nimboconone, limocinol, limocinone, kulactone, odoratone¹⁴. Some of the *in vitro* experiments suggested that protolimonoid structures such as euphane, tricallane or butyrospermol (Δ^7 isomer of euphol) might act as biosynthetic precursors for limonoids¹⁴. Azadirachtol, azadirachnol, azadirol and diepoxyazadirol are some of the *apo*-protolimonoids isolated and characterized from neem¹⁴. *Apo*-protolimonoids are rearranged from protolimonoids by the introduction of oxygen at C-7 with concomitant migration of the C-14 methyl group to C-8¹⁴. It is suggested from the previous studies and prediction that *apo*-rearrangement of butyrospermol may lead to the formation of other limonoids in the proceeding steps^{14,112}.

Of the limonoids, isolated and characterized from neem, azadirachtin represents one of the highly complex limonoid in neem¹¹². The molecule of azadirachtin has three carbocyclic and five heterocyclic rings and contains 16 stereogenic centres, of which, 7 are fully substituted¹¹³. It has a plethora of oxygen functionality, comprising enol, ether, acetal, hemi-acetal and tetra-substituted oxirane, as well as a variety of carboxylic esters¹¹³. Different structural analogues of azadirachtin has been reported such as A, B, C, D, E, F, H, I, K, M, N, vepaol, 3-deacetylazadirachtin^{113,14}. The dihydrofuran acetal moiety of azadirachtin is said to be mainly responsible for its anti-feedant activity, while the decalin fragment is known to be responsible for the observed insect growth regulation (IGR) and development effects^{113,114}.

1.9. Chemical synthesis of limonoids

The formidable challenge that makes chemical synthesis of limonoids a difficult task are the chemical complexity due to multitude of stereogenic centres, high density of oxygen atoms, its instability at acidic and alkaline pH, high temperature, light etc. Limonoids such as azadiradione, azadirachtins have been chemically synthesized so far in the laboratories^{115,116,117,27}. As the potential of neem tree to relieve global problem such as environmental stress is realized, Ley *et al.* at Imperial College, London and later at Cambridge University took efforts for the total synthesis this complex insecticidal molecule, azadirachtin A and could succeed in 2008, after three decades of constitutive success and failure stories^{118,117,116}. Seventy one steps are involved in the total synthesis of azadirachtin which gave a final yield of 0.00015%^{116,117} and stereoselective

azadiradione synthesis was accomplished in twenty steps starting from *trans, trans* farnesol as a starting material¹¹⁵. These synthetic limonoids synthesis requiring quite a lot number of steps makes it unlikely to be possible to make on any scale. In order to obtain these bioactive metabolites through biosynthetic means, understanding of its biosynthetic pathway is highly essential.

1.10. Biosynthesis of limonoids in *Azadirachta indica*

Besides the remarkable knowledge on the potential bioactivity of neem limonoids, very little is known about their biosynthetic pathway (Figure 1.3). Limonoid biosynthetic pathway deviates from the steroid biosynthesis¹¹⁹ at the formation of triterpene skeleton, through cyclization of 2,3(*S*)-oxidosqualene catalyzed by triterpene synthase. Oxidosqualene is formed by epoxidation of squalene (30C), which is formed through non-head-to-tail, 1'-1' condensation of two units of farnesyl pyrophosphate (FPP)¹²⁰ catalyzed by squalene synthase. FPP is formed through the most common chain elongation reaction by the coupling of isopentenyl pyrophosphate (IPP) with its allylic pyrophosphate, dimethyl allyl pyrophosphate (DMAPP) or with geranyl pyrophosphate (GPP)^{121,122-124,125,126}. In higher plants, biosynthesis of isoprenoid precursor, IPP and its isomer, DMAPP occurs through either of the two biosynthetic pathways: mevalonate pathway (MVA) or the methyl-erythritol phosphate pathway (MEP) or through combination of both the isoprene pathways^{127,122,121,125, 127, 132}.

The pathway uses key enzymes such as oxidosqualene cyclases, which construct the basic triterpenoid skeletons, cytochrome P450 monooxygenases, which mediate oxidations and acetyltransferases, which performs acetylation of some of the functional groups.

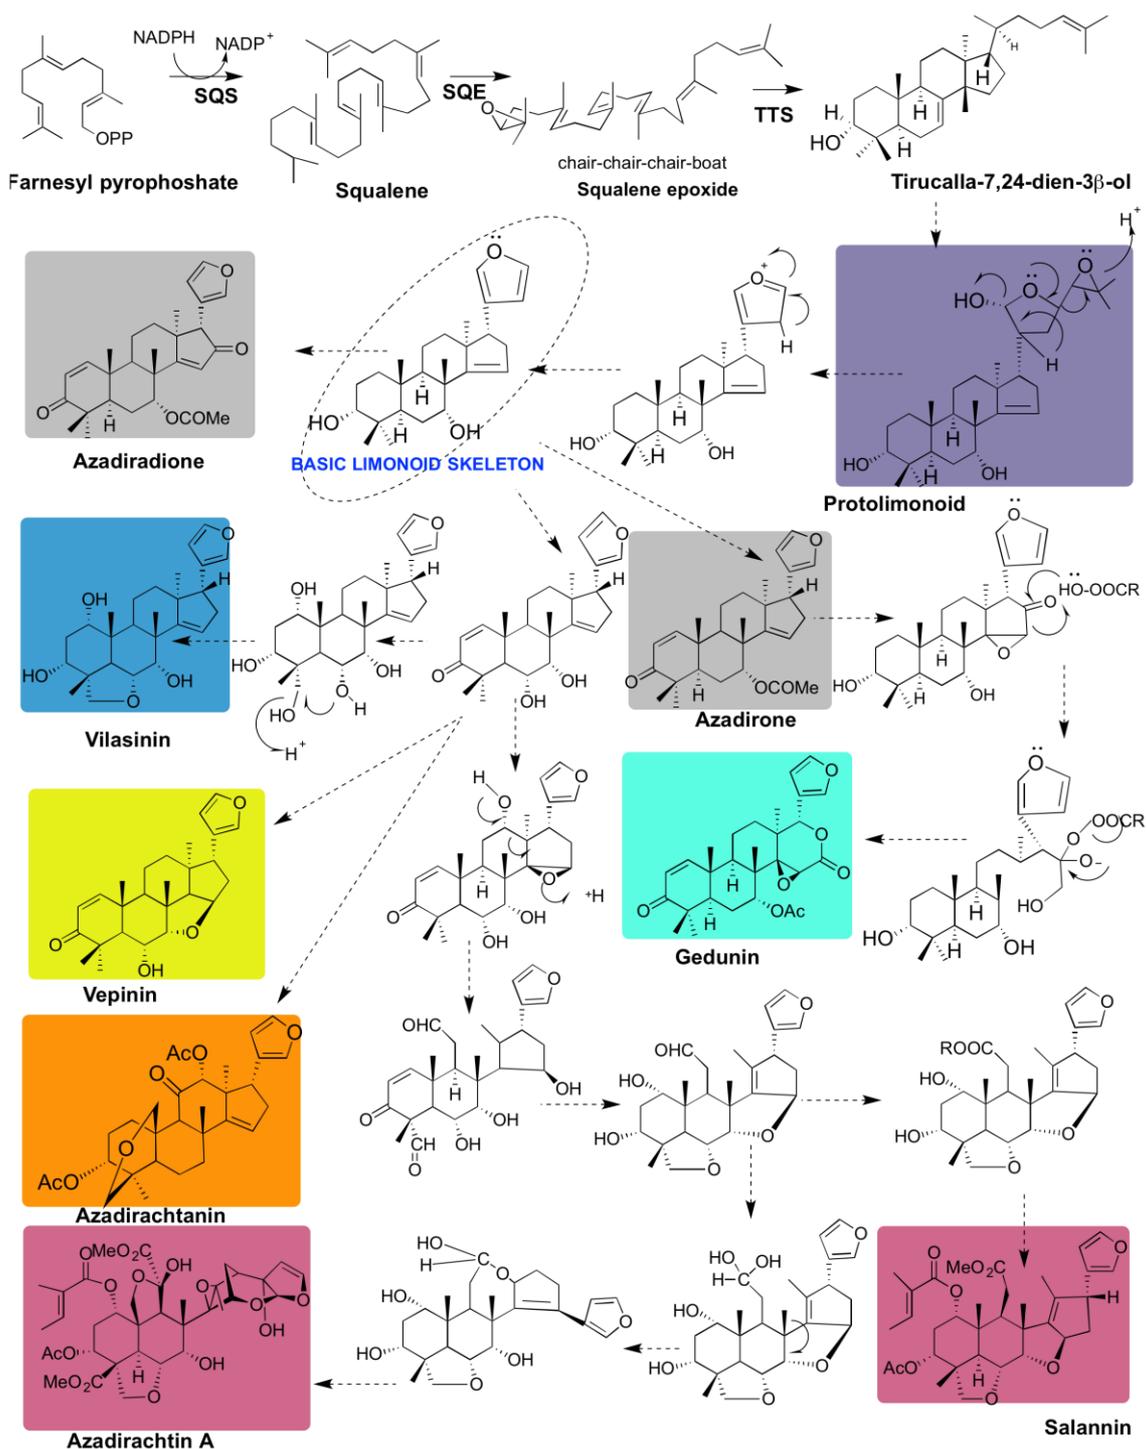

Figure 1.3. Proposed scheme and mechanisms for the formation of different limonoid skeletons.

1.11. Isoprenoid biosynthesis

The first recognition of isoprene as a repetitive motif in natural products was provided by Wallach (1887)¹²⁸. He isolated isoprene from the pyrolysis products of turpentine oil¹⁰⁷, which is mainly composed of monoterpenes such as α -pinene, β -pinene and lower proportions of carene, camphene, dipentene, and terpinolene. He found that

head-to-tail condensation of branched C₅ units was the origin for all terpenoids¹²⁸. This simple rule did not fit with many isoprenoid structures found later. An extended biogenetic isoprene rule was proposed by Ruzicka who studied the structures of various isoprenoids¹²⁹ and validated its consistency with known structures.

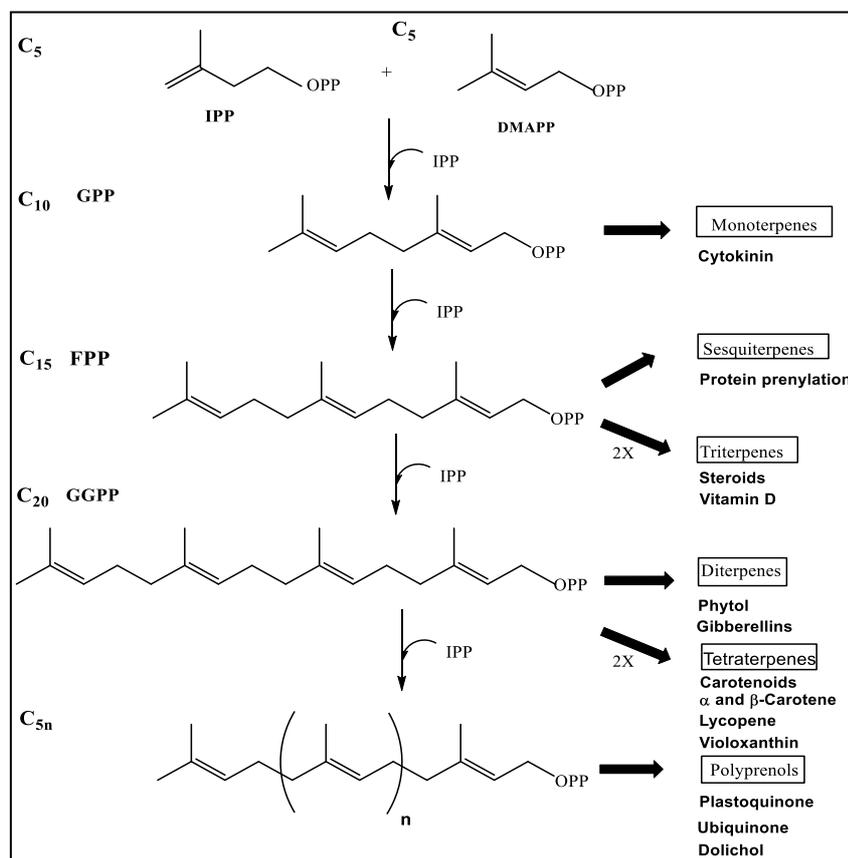

Figure 1.4. Biosynthesis of isoprenoids of various classes from C₅ isoprene unit

Isoprenoids (terpenoids) are biosynthesized through condensation reaction of the C₅ isoprene units, isopentenyl pyrophosphate (IPP) and its isomer dimethylallyl pyrophosphate (DMAPP). The biosynthetic scheme of different classes of isoprenoids is outlined in Figure 1.4 and has been reviewed by McGarvey and Bouvier^{128,130}. Dual pathway for isoprenoid precursor biosynthesis namely, classical mevalonate pathway (MVA) and methyl-erythritol phosphate pathway (MEP) has been identified in different living systems¹⁰⁹. Mevalonate pathway is distributed in eukaryotes such as fungi, plants, animals, whereas MEP pathway occurs in bacteria, archaea, plants and some actinomycetes, which are discussed in detail below.

1.11.1 Mevalonate pathway for Isoprenoid biosynthesis

MVA pathway was established in 1958 by Bloch and Linen, when the biosynthetic pathway of cholesterol in liver tissues and ergosterol in yeast were studied by feeding experiments with isotopically labeled precursors which brought out the phenomenon to existence that basic C₅ carbon skeleton of isoprene unit, IPP, is biosynthesized from the acetyl-CoA as precursor^{131,132,133}. Mevalonate pathway begins with the condensation reaction of three acetyl-CoA units yielding 3-hydroxy-3-methylglutaryl-CoA, which is reduced by NADPH forming the precursor mevalonic acid (MVA) constituting the first committed intermediate of this pathway¹³⁴.

Two groups initiated the study of contribution of acetate for the biosynthesis of steroids independently. Cholesterol biosynthesis was studied in liver by Little *et al.*¹³⁵ in 1950 and the ergosterol biosynthesis was studied by using mutant strain of *Neurospora crassa* incapable of forming acetate from carbon source which was supplied with exogenous acetate labeled with ¹⁴C in the methyl group and ¹³C in the carboxyl group¹³⁶. Bonner and Arreguin during the study of rubber biosynthesis speculated that three acetate molecules combined to make the isoprene subunit and proposed a scheme¹³³ starting from acetate. This was later confirmed from the identification of β-hydroxy-β-methylglutarate in *Crotalaria sp.* for the first time from the degradation studies performed with dicrotaline¹³⁷. β-hydroxy-β-methylglutarate which was structurally related to be the condensation product of acetate was not showing any activity, which was later, found that the actual intermediate was in the form of coenzyme-A derivative. No role other than that of isoprenoid precursor is known for mevalonate. Reduction of HMG-CoA occurs by HMG-CoA reductase (HMGR), which was considered to be the rate-limiting step in this pathway¹³². Further, isopentenyl pyrophosphate (IPP) is formed from mevalonic acid by decarboxylation and phosphorylation by the consumption of 3 ATP molecules¹³¹. This pathway was believed to be the only source of isoprene biosynthesis in all living organisms ubiquitously until the discovery of non-mevalonate pathway¹²¹. Study of this pathway has significance in the field of medicine. Some of metabolites produced by some microbes and synthetic drug mimic the structure of MVA pathway intermediates, which can be used to slow down the synthesis of isoprene units through this pathway¹³². For example, a statin drug, mevinolin, the inhibitor of this pathway has been used as a cholesterol lowering agent in humans¹³².

1.11.2 Methyl-erythritol Phosphate pathway

Non-mevalonate pathway for isoprenoid biosynthesis was first discovered by Gerard Flesch and Michel Rohmer (1988)^{138,139}. This pathway is present in bacterial and in plastids of the prototrophic organisms¹²³. The enzymes of this alternate “non-mevalonate” pathway (also called Rohmer pathway) are unique and do not use any of the enzymes of mevalonate pathway¹⁴⁰. The pathway comprises 8 steps¹⁴¹ and the first dedicated step is the synthesis of 1-Deoxy-D-xylulose 5-phosphate (DOXP) from pyruvate and glyceraldehyde-3-phosphate (GAP), which is catalyzed by thiamine pyrophosphate (TPP) dependent DOXP synthase (DXS) through transketolase-like decarboxylation reaction. In the second step, 2-C-methyl-D-erythritol-4-phosphate (MEP) is formed from DOXP through intramolecular rearrangement and reduction step catalyzed by enzyme DOXP reductoisomerase (DXR) in the presence of NADPH¹²⁴. The next step of the pathway is the conversion of MEP to 4-(diphosphocytidyl)-2-C-methyl-D-erythritol (CDP-ME) in a cytidine triphosphate (CTP)-dependent reaction catalysed by CDP-ME synthase. Further step in pathway is the phosphorylation of 2-hydroxy group of CDP-ME converting into 4-(diphosphocytidyl)-2-C-methyl-D-erythritol-2-phosphate (CDP-ME2P) by an enzyme termed as CDP-ME kinase. The next step in this pathway is the transformation of CDP-ME2P into a cyclic intermediate 2-C-methyl-D-erythritol-2,4 cyclodiphosphate (MECP), catalyzed by MECP synthase^{124,142}. ME cyclodiphosphate was then converted into 1-hydroxy-2-methyl-2-(E)-butenyl-4-diphosphate under the catalysis of 1-hydroxy-2-methyl-2-(E)-butenyl-4-diphosphate synthase^{124,142}. The final enzyme 1-hydroxy-2-methyl-2-(E)-butenyl-4-diphosphate reductase converts the above substrate into isopentenyl pyrophosphate (IPP) and dimethylallyl pyrophosphate (DMAPP) by intramolecular skeletal rearrangement¹⁴³. The pathway has been extensively studied by Rohmer, Lichtenthaler and many other research group^{124,142,109,144,132,145,146,147,148,149,139,150,145,141,151,111} and it is summarized in Figure 1.5. Study of the enzyme structures and function of this pathway has furthered the advancement in drug discovery for parasite and microbial diseases^{140,141,146,147}. As these organisms possess only MEP pathway for the biosynthesis of isoprene units, drugs which blocks this pathway of parasites and bacteria affecting human will not have side effects on humans, mammals possess only MVA pathway for isoprenoid biosynthesis. For example, fosmidomycin, natural antibiotic from *Streptomyces lavendulae*¹⁵² an inhibitor of DXR reductoisomerase completely inhibited bacterial (*E. coli*) growth at 6.25

$\mu\text{g}/\text{mL}^{132,139}$. Drugs inhibiting this pathway has been effective against malarial parasite *Plasmodium falciparum*^{132,140,141}. Another drug ketoconazole, is a derivative of a soil-applied herbicide, clomazone, also known as dimethazone exhibited antibacterial activity against the pathogenic bacterium, *Haemophilus influenzae*, with an MIC value of $12.5 \mu\text{g}/\text{mL}^{153}$. Further, the metabolites involved in photosynthesis such as chlorophyll, carotenoids, tocopherols, phytols are biosynthesed through this pathway and flux through this pathway is accelerated in the presence of light, which shows that circadian clock and feedback control exists for the diurnal control of the MEP pathway^{140,138,139,144,145,146}. Thus, plant serves as excellent model system for identification of potential drugs.

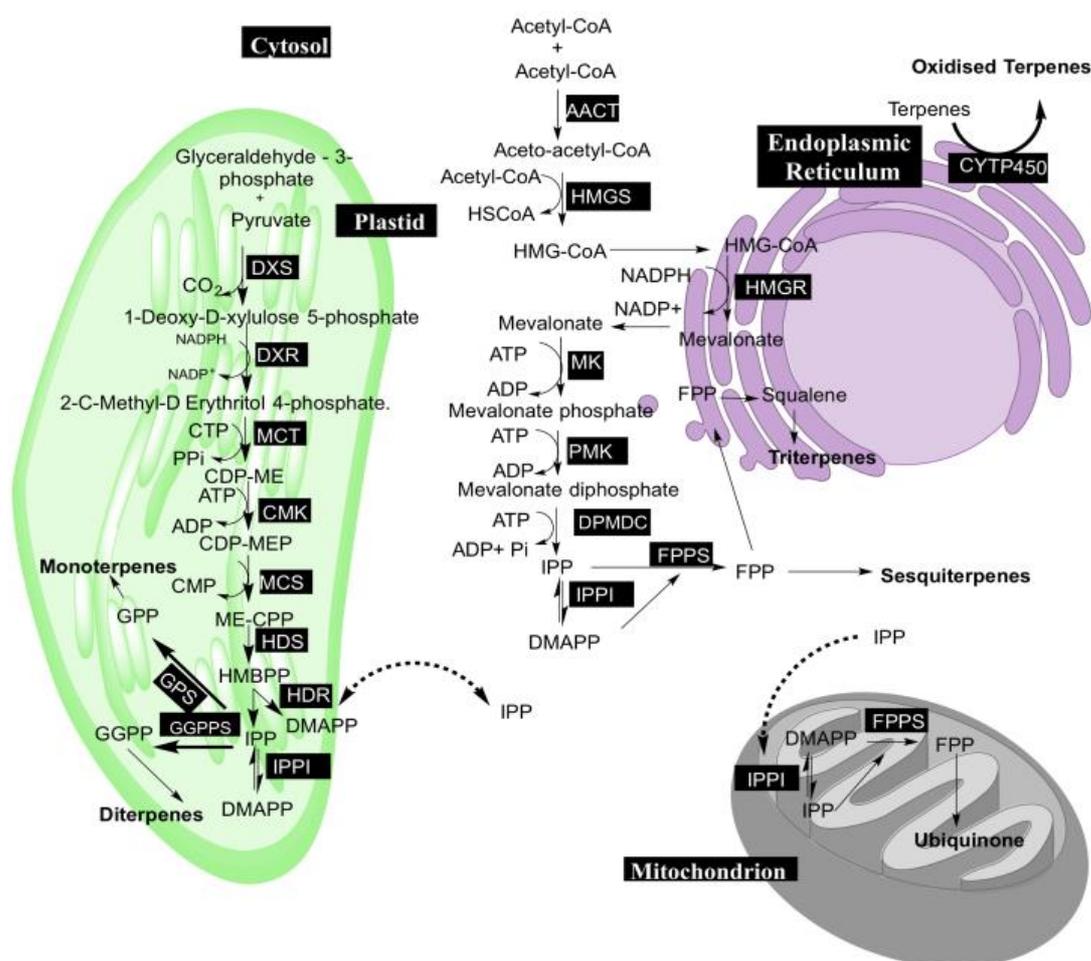

Figure 1.5. Compartmentation and localization of different isoprenoids in a plant cell. Enzyme abbreviations. AACT, acetoacetyl-CoA thiolase; HMGS, 3-hydroxy-3-methylglutaryl-CoA synthase; HMGR, 3-hydroxy-3-methylglutaryl-CoA reductase; MK, mevalonate kinase; PMK, 5-phosphomevalonate kinase; DPMDC, 5-diphosphomevalonate decarboxylase; IPPI,

IPP-DMAPP isomerase; DXS, 1-deoxy-D-xylulose-5-phosphate synthase; DXR, 1-deoxy-D-xylulose-5-phosphate reducto-isomerase; MCT, 2-C-methyl-D-erythritol-4-phosphate cytidyltransferase; CMK, 4-(cytidine 5-diphospho)-2-C-methyl-D-erythritol kinase; MCS, 2-C-methyl-D-erythritol-2,4-cyclodiphosphate synthase; HDS, 1-hydroxy-2-methyl-2-(*E*)-butenyl-4-diphosphate synthase; HDR, 1-hydroxy-2-methyl-2-(*E*)-butenyl-4-diphosphate reductase, FPPS, Farnesyl pyrophosphate synthase; GPS, geranyl pyrophosphate synthase; GGPPS, geranylgeranyl pyrophosphate synthase.

1.12. Localization of isoprenoid biosynthesis in plant cells

In plant systems, these two parallel pathways involved in the biosynthesis of differential isoprenoid end products occur in different cellular compartments¹²⁴. Classical MVA pathway is localized in the cytosol of the plant cell, whereas MEP pathway occurs in the plastids (Figure 1.5). In plants, monoterpenes, diterpenes, tetraterpenes and terpenoids involved in photosynthetic machinery (carotenoids, phytol, prenyl chain of plastoquinone) are synthesized through the plastidic MEP pathway, whereas sesquiterpenes, triterpenes, sterols and prenyl chain of ubiquinone through the cytosolic MVA pathway¹²². However, in addition to this general rule, few pieces of research have found that FPP synthase is also found to be present in the plastids in rice, wheat and tobacco¹⁵⁴. Surprisingly, in tomato, sesquiterpenes (+)- α -santalene, (+)-endo- β -bergamotene, and (-)-endo- α -bergamotene are found to be formed in the plastids through novel pathway from Z,Z -farnesyl pyrophosphate catalyzed by plastidial zFPPS^{155,156}. The labeling experiments with ¹³C-labeled mevalonate and ²H-labeled 1-deoxy-D-xylulose have confirmed that the biosynthesis of IPP occurs at two sites¹²⁷. Isoprenoid biosynthesis occurs in three subcellular locations in plant cells. The plant MVA pathway is again localized in three cellular compartments: cytosol, Endoplasmic reticulum, and peroxisome. Most of the mevalonate pathway enzymes are localized in peroxisomes, which has been identified in plants and mammalian cells through GFP tagging of the genes of this pathway whereas HMG-CoA reductase (HMGR) is partly localized to endoplasmic reticulum¹⁵⁷.

Plant sterols such as sitosterol, stigmasterol, campesterol were shown to be biosynthesized through MVA pathway in *Lemna gibba* and in *Daucus carota* by Lichtenthaler¹²³. The prenyl chain of ubiquinones are derived from the isoprene units formed from MVA pathway¹⁵⁸, synthesis of which is localized to mitochondria. Biosynthesis of diterpenes such as Ginkgolide A, is compartmentalized to plastids¹³⁹. The biosynthetic origin of monoterpenes of *Pelargonium graveolens*, *Thymus vulgaris*,

Mentha pulegium was reported to be through MEP pathway¹⁵⁹. Exclusive operation of MEP pathway for the biosynthesis of the diterpenes marrubiin¹⁶⁰, salvinorin A¹⁶¹, andrographolide¹⁶² and plaunotol¹⁶³ from *Marrubium vulgare*, *Salvia divinorum*, *Andrographis paniculata* and *Croton stellatopilosus*, respectively, and hemiterpene 2-methyl-3-buten-2-ol¹⁶⁴ from *Pinus ponderosa* were evidenced by different research groups. Contribution of both the pathways for the formation of different plant metabolites are summarized (Table 1.1).

1.13. Cross-talk between the cytosolic and the plastidial pathway

Besides this division of labor for terpenoid biosynthesis in higher plants, cross-talk between these two pathways due to traversing of isoprene units (IPP and DMAPP) across the thylakoid membranes are reported in several studies¹⁰⁸. The term, ‘cross-talk’ was used for the first time by Hemmerlin¹⁶⁵ for this cooperation between both isoprenoid pathways. Labeling studies with stable isotope labeled glucose and inhibitor studies with pathway-specific inhibitors have clearly demonstrated an exchange of isoprene intermediates between compartments of the two pathways^{165,166,167,168,169}. But, the exchange of isoprene units occur either unidirectionally or bidirectionally or at only under certain physiological conditions which all differ in each plant species. In *Arabidopsis thaliana* seedlings, soon after inhibition of either one of the pathway there is an exchange of isoprene units between plastid and cytosol complementing each other for the biosynthesis of metabolites in these compartments respectively¹⁶⁸. In another independent study in *Arabidopsis thaliana* seedlings, it was found that there was minor contribution of MVA pathway for Gibberellin biosynthesis, when the MEP pathway was blocked and when MVA pathway was blocked, sterol biosynthesis was supported by MEP pathway¹⁶⁶. In tobacco Bright Yellow-2 (TBY-2) cells, the growth inhibition due to perturbation by pathway specific inhibitors was complemented by the isoprene units synthesized from the other pathway, which showed that there was an exchange of isoprenes between the compartments under the conditions of physiological stress by inhibitors¹⁶⁵. Substrate transport assays conducted in intact chloroplasts of *Brassica juncea*, *Brassica oleracea*, *Spinacea oleracea* recorded that plastid membranes possessed a unidirectional proton symport system for the export from plastids, of specific isoprenoid intermediates, isopentenyl pyrophosphate and geranyl pyrophosphate with high efficiency and with low transport rates for farnesyl pyrophosphate and

dimethylallyl pyrophosphate involved in the metabolic cross talk between cytosolic and plastidial pathways¹⁷⁰. The sesquiterpene lactone, artemisinin from the plant *Artemisia annua* has also been shown to be synthesized from both pools of isoprene precursors¹⁷¹. Respective contributions of two pathways toward formation of dolichols in *Coluria geoides* hairy root culture studied by feeding labeled glucose showed through NMR and mass spectrometric analysis that both pathways contribute for the isoprene units incorporated into polyisoprenoid chains, but in a differential way which was further confirmed by pathway-specific precursors [5-²H]-mevalonate or [5,5-²H₂]-deoxyxylulose, both of which were incorporated into dolichols and by inhibition of dolichols synthesis by inhibitors of the respective pathways mevinolin and fosmidomycin. Initial 13 isoprene units incorporated was found to be synthesized in plastid, which was supplied from both the pathways and the later part of polyisoprenoid chain was made of isoprene units solely from MVA pathway which culminated in the conclusion that there is a unidirectional flow of isoprene units from cytosol to plastid, but not in reverse¹⁶⁹. The transport direction is of *vice versa* to the former studies reported independently by Bick *et al.*¹⁷⁰, Dudareva *et al.*¹⁷² and by Hampel *et al.*¹⁷³ for the biosynthesis of sesquiterpene, β -caryophyllene.

Labeling studies revealed that there is a differential contribution of isoprene units from the two pathways in the biosynthesis of metabolites. When studying the ¹³C-labeling of the diterpene ginkgolide from ¹³C-glucose, three isoprenoid units were found to be labeled *via* MVA pathway and the fourth isoprenoid unit *via* DOXP/MEP pathway¹³⁹. In Chamomile, sesquiterpenes bisabolol oxide A and chamazulene, when analysed, showed that two of the isoprene building blocks were predominantly formed *via* the new triose:pyruvate pathway whereas, the third unit was of mixed origin, being derived from both the mevalonic acid pathway and the triose:pyruvate pathway¹⁷⁴. This biosynthetic inequality was also observed in *Torreya nucifera* cell culture for the biosynthesis of the diterpene, Hinokiol, which is biosynthesized through the MVA as well as MEP route. The terminal IPP showed preferential labeling through MEP pathway and unfavourable labeling through MVA pathway¹⁷⁵. β -Sitosterol and stigmasterol from *Croton sublyratus* callus cultures were reported to be biosynthesized from isoprene units equally contributed by both the mevalonate pathway and the DOXP pathway¹⁷⁶. Apart from the exchange of isoprene units, geranyl pyrophosphate (GPP) is also found to cross the plastidial membrane act as substrate for enzymes in cytoplasm^{177,178}. Expression in tomato fruit

cytosol, *Ocimum basilicum* α -zingiberene synthase (ZIS) possessing both mono- and sesquiterpene synthase activity along with plastidial expression of heterogenous GPPS-SSU resulted in increased production of monoterpene products compared to expression of ZIS alone¹⁷⁷. But no such cross over of FPP and GGPP has been observed so far¹⁵⁶.

Table 1.1. Contribution of two pathways (MVA and MEP) to the synthesis of different isoprenoids in different domains of life.

1.14. Tissue specific metabolic compartmentation of limonoids

Tissue-specific metabolic profiling showed that limonoids were found to be present in different degrees of abundance in various tissues of neem¹²⁰. Fruit tissue was found to be the highest source of limonoids followed by leaves. Fruit pericarp was found to possess the highest quantity of limonoids among all tissues followed by kernel, the richest source of azadirachtin A and other C-seco limonoids (Figure 1.6). Fruit pericarp contains upto 9 mg/g tissue, azadiradione in the 2nd and 3rd developmental stages and 6 mg/g azadirachtin A in kernel at 5th developmental stage.

The limonoid profile of each of the tissues was unique in the terms of the abundance and distribution of different limonoids. Nimocinol, a ring intact limonoid is the most abundant limonoid (upto 2.5 mg/g) in the leaves of neem tree. Ring intact limonoids such as azadirone and epoxyazadiradione were the dominant limonoid in flowers comparatively. C-seco limonoid, salannin was identified to be higher in the stem tissue comparatively¹²⁰.

Though the tissue-specific profile of limonoids is known, their synthesis, localization and transport of limonoids remain uninvestigated in neem. Synthesis and localization of metabolites in specific compartments in cells and tissues of plant is controlled by several factors.

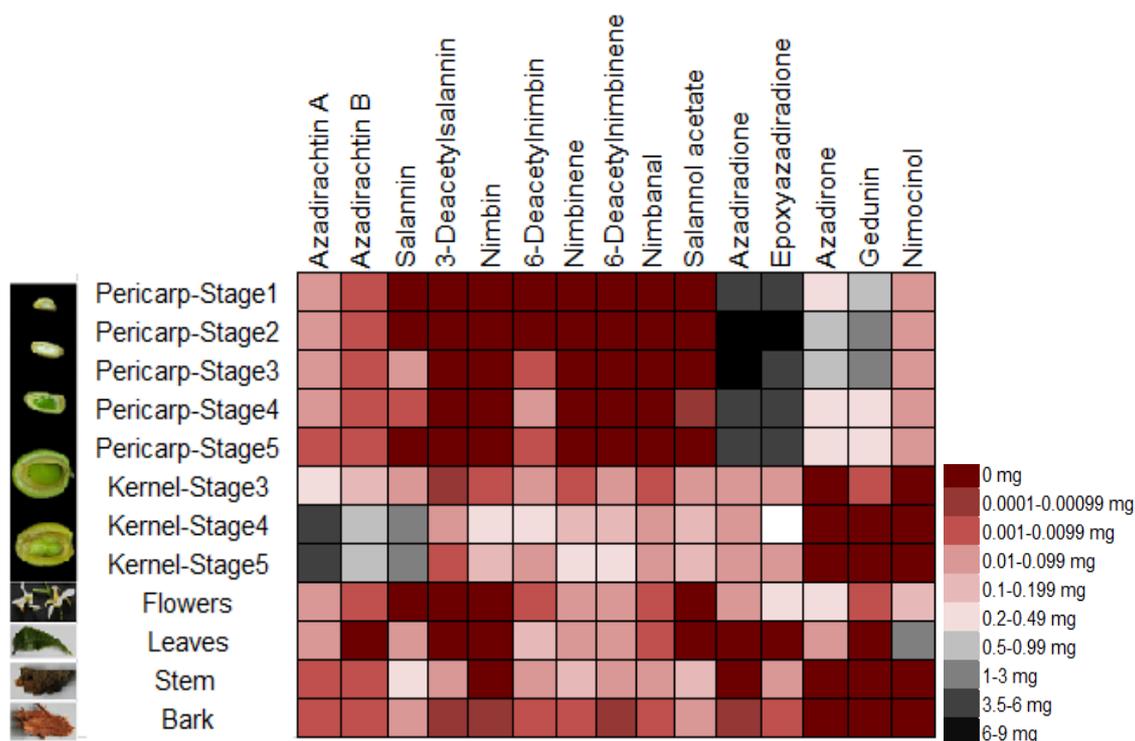

Figure 1.6. Distribution of limonoids across different tissues¹²⁰. Kernel is formed only in last three developmental stages of the fruit, pericarp from all the five developmental stages of the fruit. **Legend-** Amount of limonoids (mg/g of tissue).

1.15. Factors playing role for subcellular-localization in plants

Compartmentation is an efficient way to separate and organize various cellular processes in a cell and is achieved by several factors as follows.

1.15.2 Substrate availability

The isoprene precursors, IPP and DMAPP are biosynthesized parallel through two pathways, MVA and MEP in cytosol and plastids respectively in plants. The flux of both the pathways is independently regulated and hence the substrate pool availability in these subcellular compartments varies to a larger extent, which in turn is reflected in the yield of the terpene products generated by different terpene synthases that uses isoprene units as precursors²⁰².

1.15.2 Enzyme targeting

Some plant proteins are being targeted to multiple compartments, even though a single gene encodes them²⁰². This phenomenon of dual targeting occurs due to alternate

splicing of gene resulting in two protein variants that are targeted to two different organelles or locations²⁰². This can occur even due to tandem of targeting signals in the preprotein which are recognized by the protein import machineries of both organelles²⁰². Thus, the expression levels of the transcripts encoding for these protein variants (isoforms) occurring in different tissues determine the flux towards the end product biosynthesis²⁰². For example, in *C. roseus*, isopentenyl diphosphate isomerases (IDI), catalyzing the interconversion of two isoprene universal C5 units are transcribed as short and long mRNAs. The protein encoded by long mRNAs are transported into mitochondria and/or chloroplasts whereas the 'short' proteins, lacking the targeting signal, are localized in peroxisomes²⁰³. Apart from this type of regulation, secondary metabolite biosynthesis can occur in specific compartment or cell type by expression of the mRNA encoding for the biosynthetic enzymes only in that cell type. To exemplify, toxin, thapsigargin biosynthesis occurs in secretory ducts and the transcripts encoding for the enzymes are found to be localized in the epithelial cells surrounding the ducts²⁰⁴.

1.15.3 Transporters involving in transfer of metabolites

Most of the metabolites are not membrane permeable and transport of the metabolites is facilitated by intracellular transporters, which helps in partitioning the intermediates of a metabolic pathway across cellular compartments^{205,206,202}. In plants, MATE (Multidrug And Toxic compound Extrusion) transporter, ABC (ATP- Binding Cassette) transporter and NPF (NITRATE TRANSPORTER 1/PEPTIDE TRANSPORTER (NRT1/PTR) Family) transporters^{207,208} plays a major role for transportation of metabolites across membranes. MATE transporter uses H^+/Na^+ gradient across membrane to drive toxic compounds out of the cytoplasm. One of the transporters of MATE family, in *Nicotiana tabacum*, called jasmonate-inducible alkaloid transporter1 (Nt-JAT1) localized in the leaf cell tonoplast plays an important role in the efflux of nicotine into the vacuoles of the leaves, especially after its xylem mediated translocation from root, its site of biosynthesis, to leaves²⁰⁹. Among ABC transporters, most of them have been found to localize in the vacuolar membrane and supposedly are involved in the sequestration of secondary metabolites. It is involved in the transport of metal ions, primary and secondary metabolites that is energized by ATP²¹⁰. NPF transporters are involved in transport of several type of hormones and metabolites such as Auxin, ABA, and glucosinolates²⁰⁷. For example, in *Catharanthus roseus*, the

transporters such as CrNPF2.4, CrNPF2.5 and CrNPF2.6 are capable of transporting iridoid glucoside intermediates across different cell types thereby aiding pathway orchestration²¹¹. Additionally, another transporter CrNPF2.9, in epidermal cells is involved in intracellular movement of metabolites. This transporter exports strictosidine, the central intermediate of this pathway, into the cytosol, once it is biosynthesized from its imported precursors, secologanin and tryptamine in the vacuole²¹². Thus at cellular level, substrate channeling to enzymes is accomplished by sub-cellular or sub-structural compartmentation. At molecular level, increase in substrate availability to enzymes is facilitated by the formation of multi-enzyme complexes (metabolon formation)²¹³.

1.16. Metabolic channeling in biosynthesis of metabolites

In addition to cellular and sub-cellular compartmentation existing for the natural product biosynthesis, sequential enzymes in a pathway are organized in close proximity, called metabolons which helps in efficient channeling of the intermediates, thereby preventing undesirable metabolic cross-talk, leakage of potentially toxic intermediates^{213,214,215}. Metabolic channeling expedites the transit of metabolic intermediate from active site of one enzyme to that of the next and helps in rescuing the dilution of intermediates into bulk phase of the cell²¹³.

The metabolon formation can also be in the form of transient structures occurring through the dynamic process of assembly and disassembly, which help plants to change the profile rapidly to encounter the biotic and abiotic stress²¹⁵. Metabolons can be studied by Fluorescence correlation spectroscopy (FCS), Co-immunoprecipitation (Co-IP), Tandem affinity purification (TAP) method, Yeast-2-hybrid methods, Fluorescence resonance energy transfer (FRET) etc.²¹⁶. Well studied metabolon formation in primary metabolic pathways have been documented for glycolysis, calvin cycle, tricarboxylic acid cycle, fatty acid oxidation etc, whereas in secondary metabolic pathways, cyanogenic glucoside dhurrin biosynthetic pathway metabolon in sorghum has been archived²¹⁴⁻²¹⁶.

1.17. Technologies to study metabolite compartmentation

Study of metabolite compartmentation involves advanced and specific metabolomics tools probing organelle or specific cell of interest, which varies according to the aim of the investigation^{217,218,219–222,223}. Some of the strategies to elucidate these factors include stable isotope labeling, non-invasive analysis of metabolites using FRET sensors, single-cell metabolomics, non-aqueous fractionation (NAF) and traditional methods such as immunohistochemical analysis, organelle or protoplast preparations are coupled with different microscopic techniques and non-targeted or unbiased metabolic analysis respectively (Figure 1.7)^{202,224}. Non-targeted analysis can be performed by metabolic fingerprinting, where no chromatographic separation is performed before MS analysis or through metabolic profiling which requires chromatographic separation prior to mass spectrometric analysis^{225,226}. Commonly used hardware platforms for metabolic profiling in plant biology includes GC-MS, LC-MS and NMR^{227–233,234,235,236}. Protoplast isolation followed by fractionation of it into different populations can help in profile different cells separately. Further cellular organelles can be release from protoplast and fractionated to study its metabolite content²²⁶. Non-aqueous fractionation allows the identification of compartment specific metabolites by generation of gradient by application of a mixture of two non-aqueous organic solvents followed by separation of individual gradients and its metabolites which can be interpreted by computational analysis²³⁷. In this technique, the metabolism of the sample is arrested by snap-freezing followed by homogenization and freeze drying of it before introducing into the organic solvent system²²⁶. Live single-cell mass spectrometry helps in identification of metabolites to macromolecules and thereby, it aids in understanding the behavior of individual cells. The mass spectrometric detection was accomplished from a live single cell or even an organelle by drawing out the cell contents by a metal-coated microcapillary (nanospray tip) under video-microscopy and directly feeding into a mass spectrometer via a nano-electrospray ionization plume²³⁸. The technical advances in metabolomics have taken new dimensions such as, spatially resolved metabolomics and mass spectrometry imaging^{226,222}. Laser assisted micro-dissection helps in the isolation of desired tissue or cell type from heterologous population followed by profiling of it for genes, proteins or metabolites^{239–241}. Metabolite imaging can be performed using Laser Ablation Electrospray Ionization (LAESI)-mass spectrometry, which maps the ions and can dissect the region specific localization of metabolites in contrasting plant organs^{242,243}. MS Imaging (MSI) technique requires matrix application over the tissue

followed by MS imaging measurement, which uses laser irradiation to desorb the analyte molecules from tissue and to ionize the molecules, it uses probe beam such as solvent stream or ion beam or laser. The ions are identified in the mass analyzers and MSI data acquired are interpreted in the form of ion map which has greatly helped in cell specific localization of *Catharanthus* terpene indole alkaloid intermediates in different cell types²⁴⁴. Furthermore, FRET based fluorescent nanosensors offers the advantage of monitoring dynamic changes in the concentration of specific or wide range of solute which in turn will help in revealing the transport of metabolites across the cells²⁴⁵. For example, in a separate study, maltose-binding protein as a prototype, nanosensors were constructed which uses PBP (Periplasmic Binding Protein) fusion with green fluorescent proteins and binding of the substrate to this chimeric protein causes changes in the PBP which increases fluorescence resonance energy transfer (FRET) between two coupled green fluorescent proteins^{246,244}. This helps in imaging the changes in concentration of specific metabolite over time by non-invasive means^{246,247}.

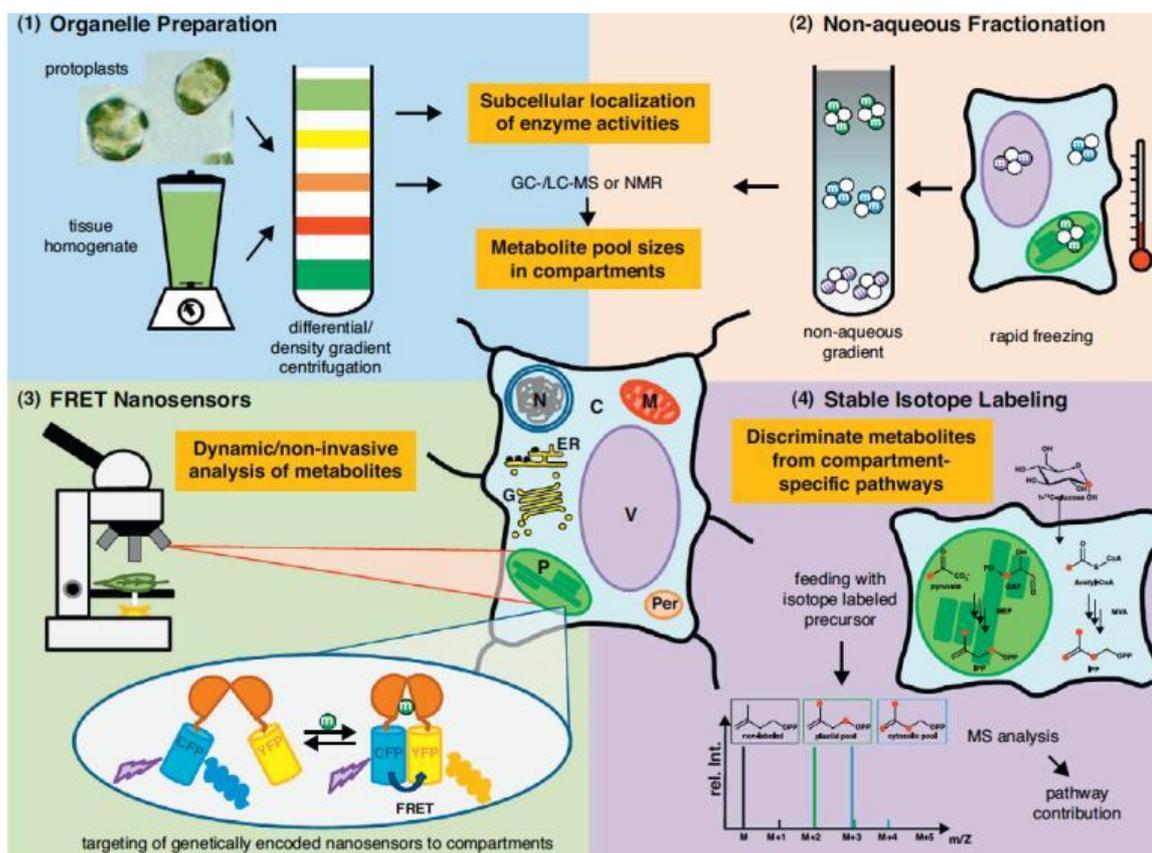

Figure 1.7. Technologies for metabolic profiling at the subcellular compartment level. (Adapted from Heinig *et al*²⁰².) Simplified scheme of a plant cell showing major compartments involved in metabolism including plastid (P), mitochondria (M), peroxisome (Per), vacuole (V), ER, golgi (G), nucleus (N), and cytosol (C). (1) preparation of organelles from homogenized tissue or protoplasts with subsequent metabolic profiling; (2) non-aqueous fractionation (3) Förster resonance energy transfer nano sensors are genetically encoded and can be targeted to multiple compartments thus allowing a dynamic and noninvasive analysis of single metabolites in living plant cells; (4) stable isotope labeling combined with MS analysis. Abbreviations: m: metabolite.

1.18. Metabolic engineering

Metabolic engineering is considered as a simplest form of synthetic biology, which deals with the construction of new biological components such as enzymes, genetic circuits or redesign of the existing biological systems for the production of secondary metabolites (Figure 1.8)^{248,249}. Synthetic biology approach can be in either of the two forms, top-down and/or bottom-up approaches. In top-down approach, exogenous genes are introduced into a tractable host system, which leads to reprogramming of its native metabolic network²⁵⁰. Bottom-up approach, involves *de novo* construction of synthetic genomes or other components behaving similar to the living systems²⁵⁰. In this cell free approach, cell's growth, regulatory network, transportation and other factors do not limit the production of metabolites²⁵⁰.

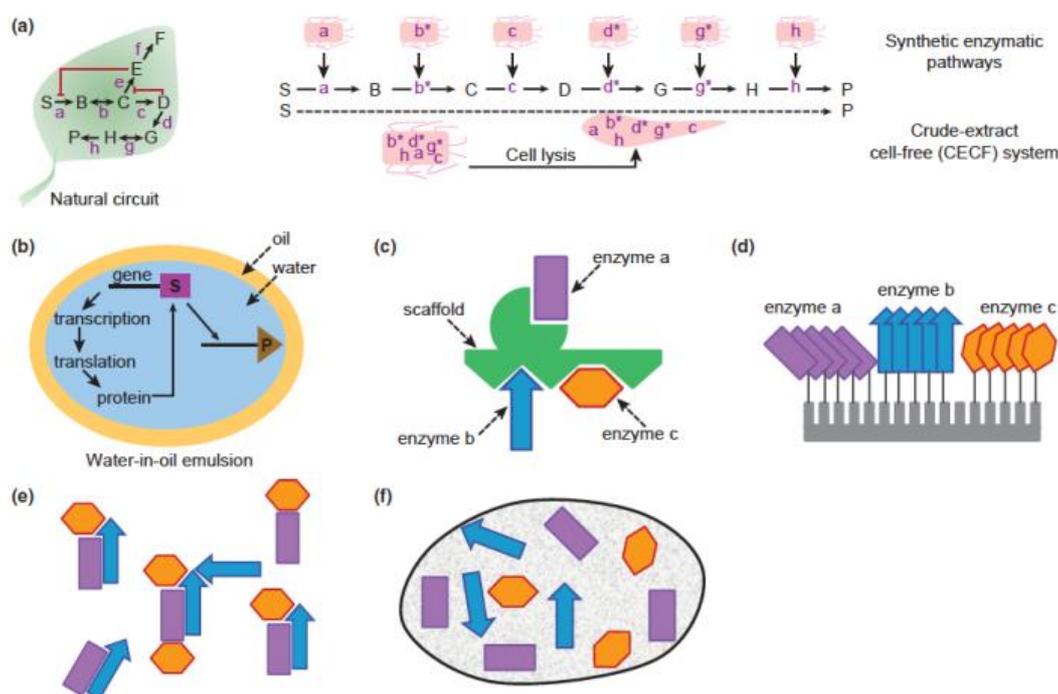

Figure 1.8. *in vitro* synthetic biology platforms (Adapted from Tessa Moses *et al.*²⁵⁰) (a) Synthetic enzymatic pathways in which purified enzymes are combined with reaction components in an aqueous environment to convert a substrate to a product through a series of reactions, (b) *In vitro* compartmentalization using water-in-oil emulsions. (c–f) Metabolic channeling brings enzymes in close proximity with their substrate (c) protein scaffolding, (d) tethering enzymes to a surface, (e) covalently linking related enzymes into aggregates and (f) foam dispersion techniques in which the enzymes are encapsulated using surfactants. a, b, c, d, e, f, g, h, native enzymes; b*,d*,g*, synthetically modified enzymes; B, C, D, E, F, G, H intermediates; P, product; S, substrate.

Metabolic engineering of terpenes have attained considerable progress by reconstructing metabolic pathway of plants in tractable heterologous systems or “platform cell factories” such as *E.coli*²⁵¹, *Aspergillus niger*, *Bacillus subtilis*, *Corynebacterium glutamicum*, Chinese hamster ovary (CHO) cells and *Saccharomyces cerevisiae*²⁵². Reconstruction of the pathway into host can be actuated by utilizing the conceptual modular structure of biosynthesis of terpenes²⁵³. First module (M1) involves the biosynthesis of prenyl pyrophosphate substrates, dimethylallyl pyrophosphate (DMAPP; C5), geranyl pyrophosphate (GPP; C10), farnesyl pyrophosphate (FPP; C15), and geranylgeranyl pyrophosphate (GGPP; C20) from IPP (C5). The second module (M2) is assigned to cyclization of prenyl pyrophosphate by terpene synthase (TPS),

which generates basic terpene skeleton. This module is again subdivided into two sub-modules M2a and M2b, which encompasses class II and class I TPS respectively. TPS of both the classes differ in their mechanism of initiation of carbocationic cyclization and rearrangement reactions. In third module (M3), these basic structures are functionalized by modifying enzymes such as cytochrome P450s, Fe(II)-dependent dioxygenases, acetyltransferases, methyltransferases, reductases, glycosyltransferases, etc.²⁵³ (Figure 1.9).

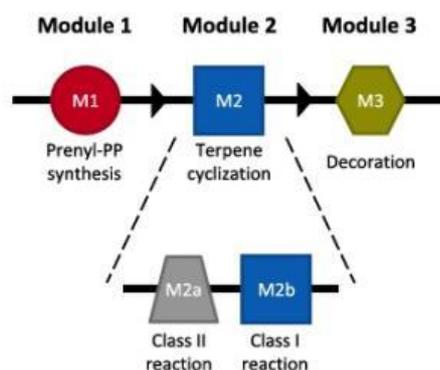

Figure 1.9. Conceptual modular structure of terpene biosynthesis (Adapted from C. Ignea *et al.*²⁵³).

Plug-and-play construction methods involve combining different module-specific parts individually and also together in the heterologous system as gene clusters help in accomplishing the following

1. Combinatorial biosynthesis of natural products
2. To produce different scaffolds of pathway intermediates utilizing the substrate promiscuity of TPS
3. Combinatorial biosynthesis to generate novel compounds
4. Single-deletion and multiple-deletion constructs can be assembled in the plug-and-play scaffold to elucidate and characterize the steps of unknown biosynthetic pathway.
5. Cryptic pathway can be activated by inserting different promoters to enhance the expression of each of the genes in the cassette^{254,255}.

Many of the medicinally important natural products and carotenoids²⁵⁶ has been engineered into heterologous system using this plug-and-play strategy. Advancements for gene editing such as clustered regulatory inter spaced short palindromic repeats (CRISPR)-cas9 has helped in one step metabolic pathway integration into tractable hosts

at any of the desired location in the chromosome²⁵⁷. Thus metabolic engineering aims not only at increasing the productivity of bioactive natural products (Figure 1.11), but also serves as a bottom-up approach for discovery of novel natural product and its biosynthetic pathway whereas, in top-down approach, biological samples from diverse environments are extracted for metabolites, screened for bioactivity and the active molecules are structurally elucidated²⁵⁸. One of the first examples of the medicinal natural product successfully been biosynthesized in *Saccharomyces* is an anti-malarial sesquiterpene lactone artemisinin and is economical when compared to extraction from natural sources. Metabolic engineering of 15 enzymes in yeast including selected genes of MVA pathway along with amorphaadiene synthase, CYP71AV1, and AaCPR yielded upto 25g/L of artemisinic acid²⁵⁹. Whereas, introduction of all the genes of MVA pathway along with the above mentioned genes gave production of >40 g/L of the intermediate amorphaadiene under the fermentation condition of restricted ethanol feed with lower oxygen uptake rate²⁶⁰. Semi-synthetic formation of artemisinin from artemisinic acid gave 55% yield²⁶¹. Higher the number of ring systems and chiral centres it possess, more complex the metabolite is. For example, artemisinin contains 4 rings and 7 chiral centres whereas, single ring containing salicylic acid from willow bark was synthesized chemically in 2 steps achieving 90% yield²⁶². Morphine from Opium poppy has 5 ring system and 5 chiral centres and was biosynthetically produced upto 2.4 mg/L by engineering of 25 enzymes into yeast. Taxadiene, one of the intermediate in formation of taxol, an anti-cancer agent from Pacific Yew tree is biosynthesized through metabolic engineering of 6 enzymes in *E.coli* (dxs, idi, ispD, and ispF genes the MEP pathway bottlenecks in the upstream module and GGPP synthase taxadiene synthase in downstream module as synthetic operons) which yields up to 1g/L²⁶³. In addition to this strategy, targeting the biosynthetic pathway gene into specific sub-cellular compartments such as yeast mitochondria has considerable improvement in the yield. For example, in yeast 8-and 20-fold improvement was achieved in production of valencene and amorphaadiene by co-engineering the truncated and deregulated HMG1, mitochondrion-targeted heterologous FDP synthase and a mitochondrion-targeted valencene synthase, or amorphaadiene synthase²⁶⁴. These enhancements are achieved by directing the flux through MVA pathway by deregulation through overexpressing the truncated HMG1 or a mutated form of HMG2, mutated version of the sterol transcription factor UPC2²⁶⁵, since HMGR is subjected to regulation on multiple levels.

Other strategies for engineering in *Saccharomyces* can be through replacing endogenous promoters of competing pathway branches with repressible promoters. As a eukaryote, *Saccharomyces* possesses an endoplasmic reticulum (ER) that allows the heterologous expression of membrane-localized cytochrome P450 enzymes. Hence, the overexpression of heterologous protein in ER has been enhanced in a separate strategy to increase the capacity of a yeast triterpene production platform by transforming the subcellular morphology of ER, using the following gene knock-out targets²⁶⁶.

- E3 ligase-encoding HRD1 of the HMGRCoA reductase degradation (HRD) pathway, which is involved in ER-associated degradation (ERAD) of HMGR, the MVA pathway gatekeeper.
- PEP4-encoded proteinase A which is responsible for the maturation of various vacuolar peptidases as it has effect on the stability of heterologous proteins.
- PAH1, which encodes phosphatidic acid phosphatase that generates neutral triglycerides from phosphatidic acid in yeast and dysfunction of which results in drastic proliferation of outer nuclear membrane and the ER²⁶⁶.

Similarly, in plants, the redirection of terpene precursor to specific compartment such as cytosol and plastid by using separate gene constructs for patchoulol synthase (PTS) and amorphadiene synthase along with its substrate (farnesyl pyrophosphate) provider FPP synthase (FPS) targeted to the compartments helps in 1000 fold increase of the product²⁶⁷.

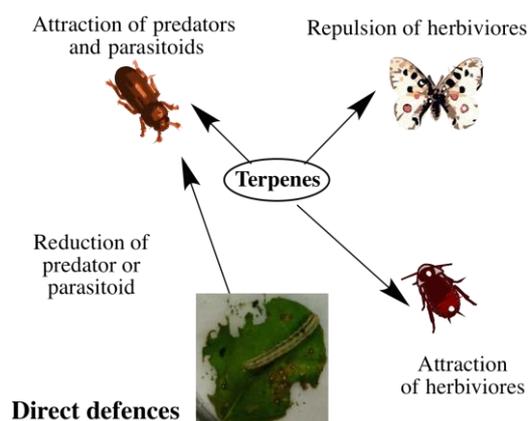

Figure 1.10. Direct and indirect defenses in plants

Apart from the production of pharmaceutically important natural products through metabolic engineering in heterologous system, overexpression or altering the genes in native host helps in improving the immunity and defense of plant and microbes against

diverse biotic stress factors in the environment. Induced indirect defense of plant includes tritrophic interaction, as in order to defend themselves against feeding herbivores, plant emit volatiles that attracts the enemies of herbivores such as predators and parasitoids (Figure 1.10)²⁶⁸. For example, introduction of new gene targeted into mitochondria involved in the biosynthesis of sesquiterpene volatiles that are not present in the volatile blend of *Arabidopsis* help in the attraction of carnivorous predatory mites which prey on the herbivores and hence are known to aid in the fitness of the plant²⁶⁹. These studies not only help for improving the fitness traits of the plant but also to understand the role of each volatiles terpenes released by plants²⁷⁰. Overexpression of transcriptional factors involved in the biosynthetic pathway of interest can also ease the improvement in production of the secondary metabolite in the native plants. Basic helix–loop–helix (bHLH) and Basic Leucine Zipper (bZIP) transcription factors are involved in many of the regulatory processes of eukaryotes whereas WRKY and AP2/ERF are involved in the regulation mechanism for the defense responses in plants²⁷¹. Overexpression of one of these factors has helped in increasing the productivity of artemisinin in *A. annua* and indole alkaloids in *Catharanthus*²⁷¹.

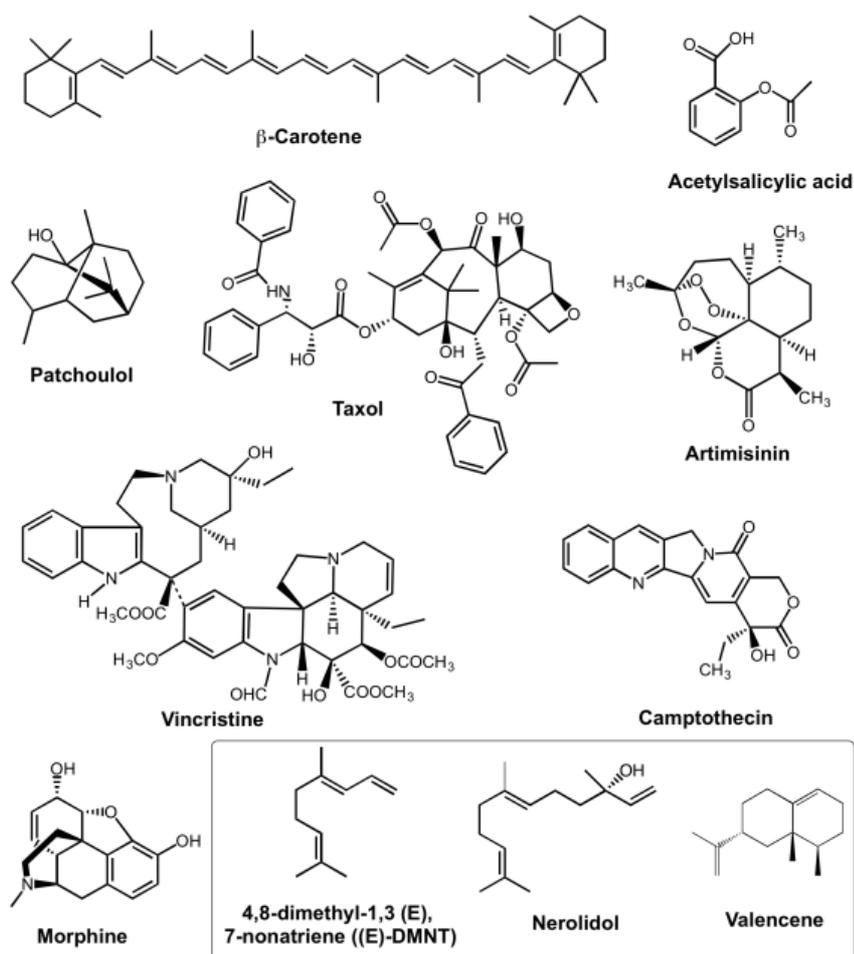

Figure 1.11. Medicinal natural products from plants in which biosynthetic pathway has been completely or partially engineered into heterologous system or semi-synthesis or total synthesis has been attempted to increase the productivity. In box- Volatile Organic Compounds (VOCs) engineered into non-host plant to study indirect plant defense.

In order to optimize the biosynthetic potential of these secondary metabolites for mankind by engineering in the native host, one must understand where their metabolism is coordinated within the cell and tissue. As biochemical steps of a single pathway occur at different subcellular locations, determination of factors such as substrate availability, enzyme localization, transport of intermediates act as an important constraint in metabolic engineering^{272,202}. In particular, plants have complicated intracellular organization with metabolite flow between compartments which are highly regulated and orchestrated between different metabolic pathways²²⁴. Targeting the enzymes to non-native compartments helps in increasing the production as if there is less competition for pathway intermediates and normal regulatory mechanisms that control

the flux of carbon down any particular biosynthetic pathway²²⁴. For example, essential-oil producing plants involved in accumulation of monoterpenes have highly specialized anatomical structures that are involved the biosynthesis and storage. Engineering of monoterpene biosynthetic pathway into plants which does not produce monoterpenes will be challenging due to non-availability of specialized secretory strictures²⁷³. Hence, limited knowledge on the subcellular compartmentation such as localization of enzymes, substrates, localization and transport of products serves as a bottleneck in metabolic engineering. Unraveling the metabolon formation, subcellular localization of enzymes and intermediates, substrate availability will strengthen the productivity and yield of natural products harnessed through metabolic engineering. In precis, the synthetic biology and different approaches of genomics have paid impetus to decipher the indigenous medicinal value to the modern world²⁷⁴.

1.19. Main objectives of the Thesis

Azadirachta indica, one of the medicinal tree producing diverse triterpenoids is well known for its insecticidal, anti-feedant limonoid azadirachtin A. The genes involved in the biosynthetic steps of the upstream pathway have been already studied, but the gene / enzyme characterization is still lacking for many biosynthetic steps in the downstream pathway. Exception from the structure, synthesis, the biological activity of different limonoids, its quantitative occurrence in different tissues, upstream few steps of the pathway other information on limonoid biosynthesis and localization has not been elucidated in this tree. Therefore, the main objectives of this thesis are

1. To identify and characterize the organelles/ intra-cellular compartments involved in the storage of limonoids in different tissues.
2. To trace the flow of carbon in limonoid skeleton through stable isotope feeding experiments.
3. To study the expression level of the genes involved in isoprene biosynthetic pathway and to characterize the putative candidate genes associated with limonoid biosynthesis.

In order to achieve the above goals, histochemical studies have been carried out for different tissues of neem and the intra-cellular organelles have been isolated for micro-metabolic profiling to identify limonoids in the intracellular organelle level. To

trace the flow of carbon through feeding experiment, *in vitro* plantlets, callus and cell suspension cultures were established as a system, and limonoid-producing ability of it has been studied. To further corroborate the participative role of MVA and MEP pathway genes with respective to limonoid synthesis, inhibitor studies and expression studies have been carried out followed by the characterization of the putative acetyl transferases involved in functionalization of limonoids in the downstream steps of limonoid biosynthesis. Thus the present studies will pave way for future thrusts such as characterization of further downstream steps of limonoid biosynthesis, regulation of the pathway, location of biosynthesis of intermediates of each step of the pathway, its intra- and intercellular transportation mechanism etc. Interrogation into above perspectives will help in overexpression of the pathway in native host or metabolic engineering into heterologous system.

Chapter 2

Development of *in vitro* cultures of neem, limonoid profiling and study of organelles and cells involved in metabolite storage

Tissue sectioning

Chapter 2: Section A
**Establishment of neem cell culture, limonoid
profiling and quantification**

2A.1. Introduction

Various parts of neem tree serves mankind since time immemorial with its bountiful medicinal properties, of these the neem seed has been used widely as a natural insecticide in agricultural practice^{1, 2}. The most active and characteristic compound of neem tree, azadirachtin A is found in most of the tissues of neem, however its occurrence is rich in the seed kernel^{3, 4}. Azadirachtin A, an effective insect growth deterrent, is found to be the best potential natural insecticide candidate identified so far from the plant sources, also possesses remarkable non-toxicity to vertebrates³. Characterization of this highly oxygenated, complex molecule was startling in such a way that it paid impetus for the perseverance of the researchers from both biological and chemical fields. In particular, following the determination of correct structure of azadirachtin in 1985⁵, Ley and co-workers achieved the total synthesis of this molecule after two decades of efforts^{6, 7}. Seventy one steps are involved in the total synthesis, but the final yield was only 0.00015%^{6, 7}, which warrants the alternative ways such as biosynthesis through tissue culture means, for the production of azadirachtin. Considering the efficient activity of biopesticide, azadirachtin A, several studies have been reported for the optimization of increasing its productivity and also the biomass of neem in cell culture and also as plants⁸⁻²². Secondary metabolite biosynthetic potential of plants varies genetically and environmentally according to geographical location and hence is the metabolite production of the *in vitro* cells derived from the explant²³. Besides these variation, cell and tissue developed *in vitro* undergoes somoclonal variation and also variation in the secondary metabolite production over time. Taken together these factors, new cell lines need to be established from the plant tissue before the initiation of experiment to establish its physiological, genetic and other characteristics. Various studies performed with neem tissue culture are callus culture¹⁰, suspension culture⁸⁻¹⁰, hairy root culture^{11, 16}, somatic embryogenesis²⁴⁻²⁷, androgenesis¹³ for the propagation of whole plant *in vitro*^{12, 28-30} aiming at increasing the population of neem tree. Somatic embryogenesis, i.e., the formation of embryo from the somatic cells of the explant has been reported to induce in the presence of different concentrations of the hormone thidiazuron (TDZ)²⁷. Hence, this serves as an effective method for mass propagation of elite neem plants followed by hardening them in green house conditions²⁷. Anther culture developed in neem helped in the production of haploid

plants thereby avoiding the heterozygous nature of the plants formed from seeds due to cross pollination (Figure 2A.1)¹³. Cell suspension culture and hairy root culture has been developed and used extensively for the large-scale production of azadirachtin A^{11, 31, 32}. Different media composition was found to have effect on the azadirachtin production from various explants obtained from different geographical conditions^{11, 20}. Hence, it is necessary to establish the suitable media and hormonal composition for the new explants, for the appropriate development of cell and organs. Moreover, also, other pharmacologically active limonoid levels were not improved so far through tissue culture as evident from the literature. The present work was carried out with the objective of developing neem plantlets, callus and cell suspension *in vitro* in order to profile them for the diversity of limonoids and thereby to study limonoid biosynthesis.

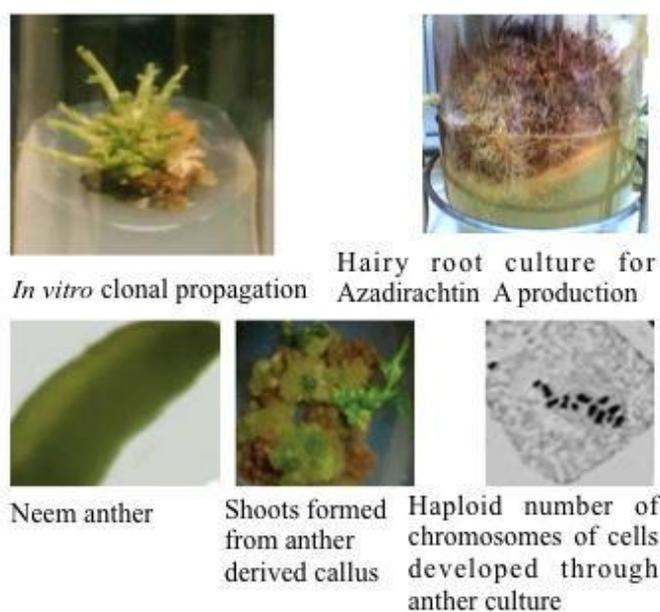

Figure 2A.1. Various neem plant tissue cultures carried out for the improved production of azadirachtin A^{8, 13, 26, 28-30}

2A.2. Results and discussion

2A.2.1. Optimization of growth regulator composition for callus

Following surface sterilization of neem fruits, the kernel was excised and inoculated over MS media supplemented with 2 mg/L 2,4- D, 1 mg/L BAP for auxin and cytokinin respectively and also over media containing 2 mg/L NAA, 0.2 mg/L BAP (Figure 2A.2). Even though the explants grown over the hormone combination 2 mg/L 2,4- D, 1 mg/L BAP showed callusing, it turned brown and fragile over time (Figure

2A.3C). The intact cotyledons showed sprouting in 2-3 weeks interval whereas the others showed callusing from the cut ends over the hormone combination 2 mg/L NAA, 0.2 mg/L BAP (Figure 2A.3A, Figure 2A.3B). Henceforth, cotyledons with the incised ends were inoculated over MS media containing 2 mg/L NAA, 0.2 mg/L BAP.

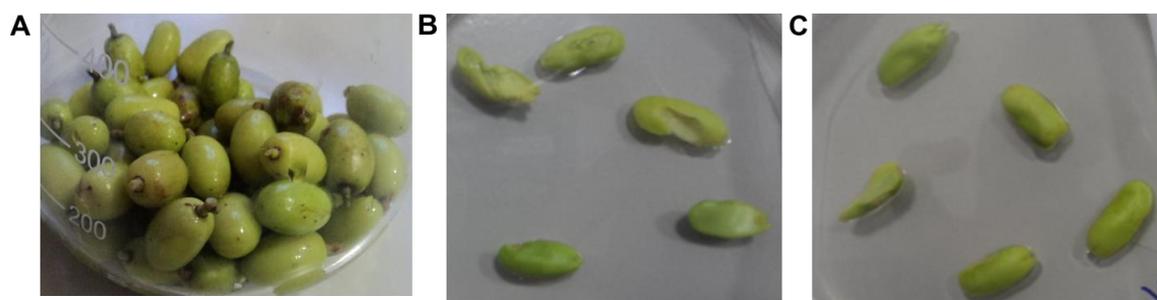

Figure 2A.2. (A) Surface sterilized neem fruits (B), (C) Kernel excised from the sterilized fruit and inoculated over MS media of different growth regulators composition

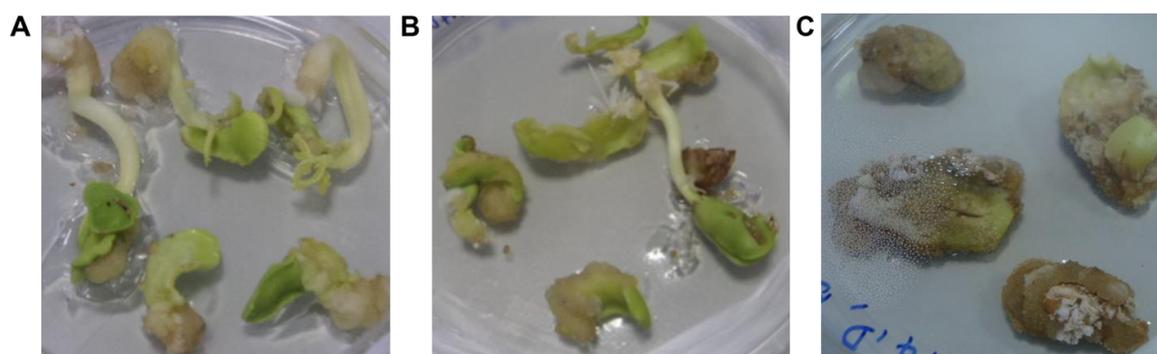

Figure 2A.3. The explant over 2-3 weeks of incubation (A) (B) Kernel explant inoculated over media with NAA and BAP. (C) Kernel explant inoculated over media with 2,4-D and BAP.

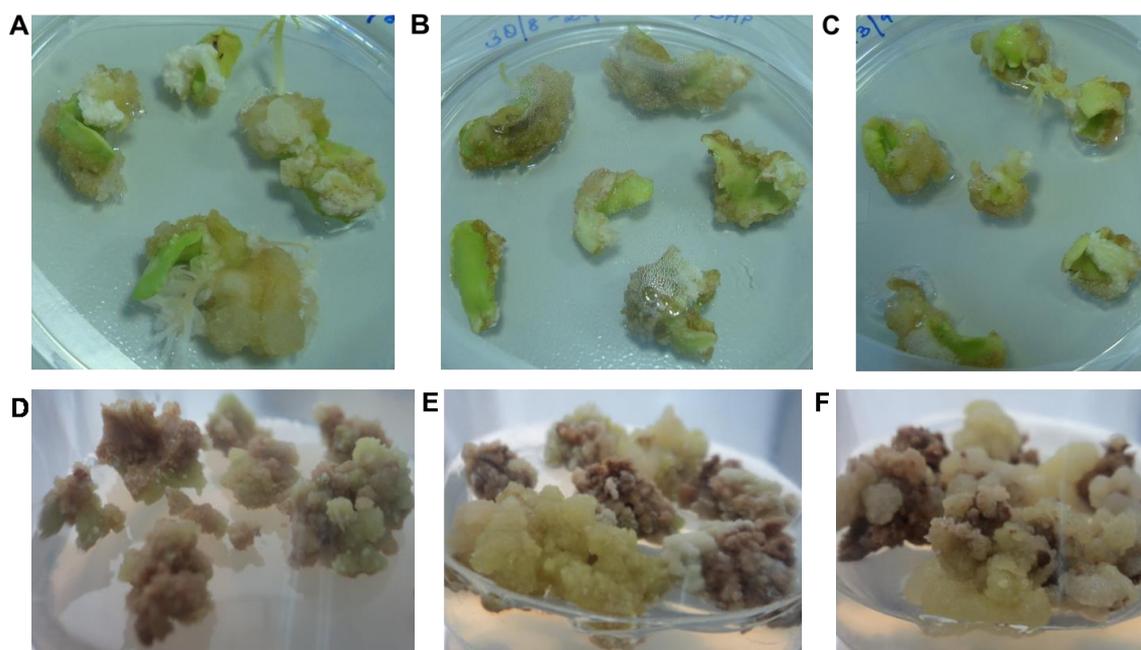

Figure 2A.4. Different stages of explant and callus (A) The explant over 4 weeks of incubation over media with NAA and BAP showing callusing **(B)** The callus developed from explant was excised after 4 weeks and re-incubated in the media of same composition **(C)** Re-incubated explant showing callusing again **(D)** **(E)** **(F)** Excised callus sub-cultured every 4 weeks and maintained in regular intervals showing difference in morphology.

Every three weeks, the newly formed callus was excised, both the parental and callus tissue were sub-cultured into media of same composition. Different calli showed different morphology, colour ranged from yellowish green, green, brown and friability, moisture content etc. (Figure 2A.4). Tight, compact callus showed better properties as it was immune to infestation when compared to loose callus with high water content. Callus was profiled for its limonoid content.

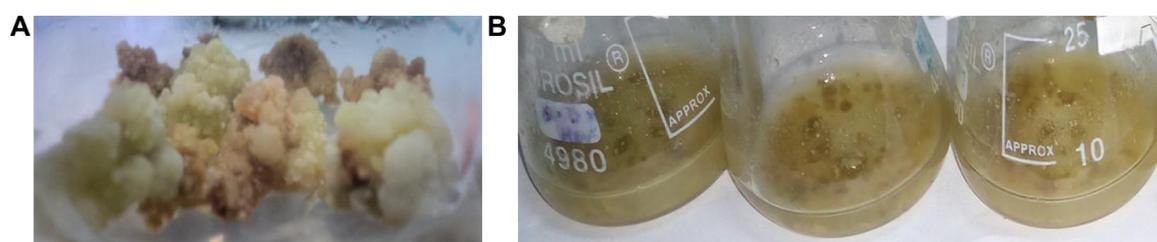

Figure 2A.5. (A) Friable callus was used for development of cell suspension culture **(B)** suspension culture developed from the friable callus.

2A.2.2. Metabolic profiling of neem callus

Limonoid profiling of callus at different subculturing stage and of different morphology was carried out using UPLC-ESI (+)-HRMS based targeted profiling by comparison with 15 limonoid standards isolated and characterized from neem (Figure 2A6).

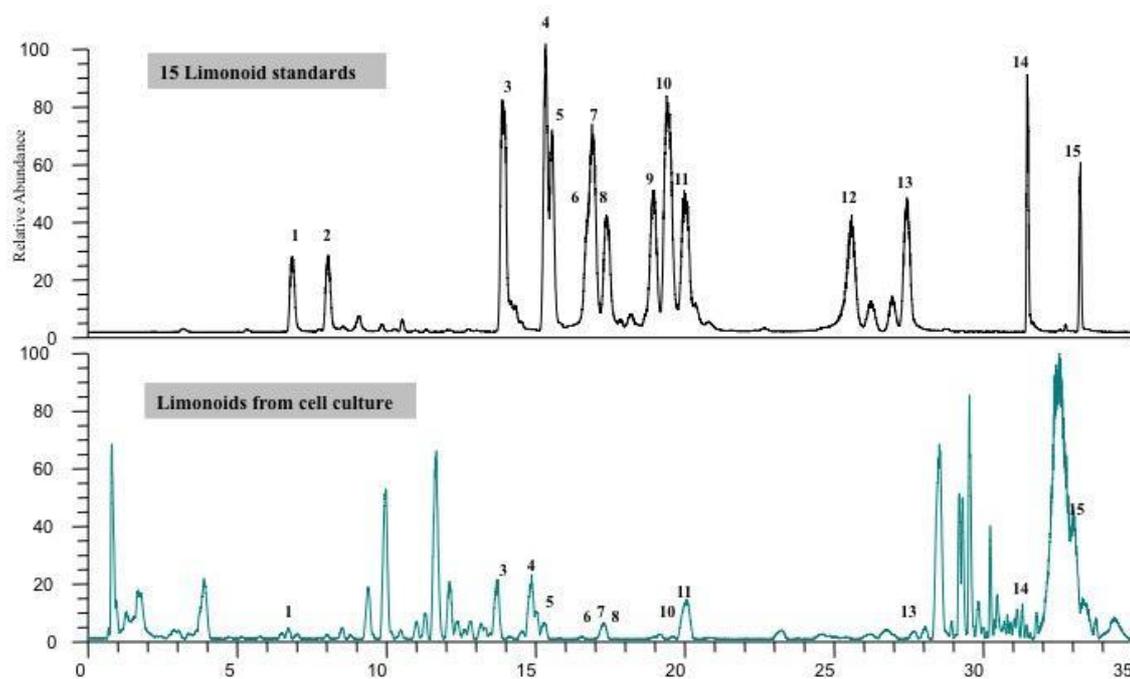

Figure 2A.6. Metabolic profiling of callus cells by comparison with 15 authentic limonoid standards isolated and characterized from neem. 1-Azadirachtin A, 2- Azadirachtin B, 3- 6-deacetylnimbin, 4- Azadiradione, 5- 6-deacetylnimbinene, 6- Nimbanal, 7- Nimbin, 8- 3-deacetylsalannin, 9- Gedunin, 10- Nimbinene, 11- Salannin, 12- Epoxyazadiradione, 13- Salannolacetate, 14- Azadirone, 15- Nimocinol.

2A.2.3. Establishment of cell suspension and neem plantelets

The callus cultures which showed limonoid formation in every sub-cultures were selected and cut finely, inoculated into liquid MS media of same hormonal composition (2 mg/L NAA, 0.2 mg/L BAP) (Figure 2A.5).

2A.2.4. Metabolic profiling of neem plantlets and cell suspension

Neem plantlets and a stable cell suspension were established from the callus culture obtained from kernel, in order to profile and quantify the individual limonoids formed and therefore to perform feeding experiments for tracing the limonoid biosynthetic pathway. Neem seedling was developed from the cotyledon in four weeks

of inoculation. Limonoid profiling was carried out using UPLC-ESI (+)-HRMS based targeted profiling from individual parts of the seedling such as leaf, root, stem and withered cotyledon. Azadirachtin A was found to be the major limonoid identified in the different part of seedling followed by azadirachtin B (Figure 2A.7). Azadirachtin A present in the stem of the plant was 123 $\mu\text{g/g}$, 100 $\mu\text{g/g}$ of root, 81 $\mu\text{g/g}$ of leaf and 7 $\mu\text{g/g}$ of withered cotyledons respectively.

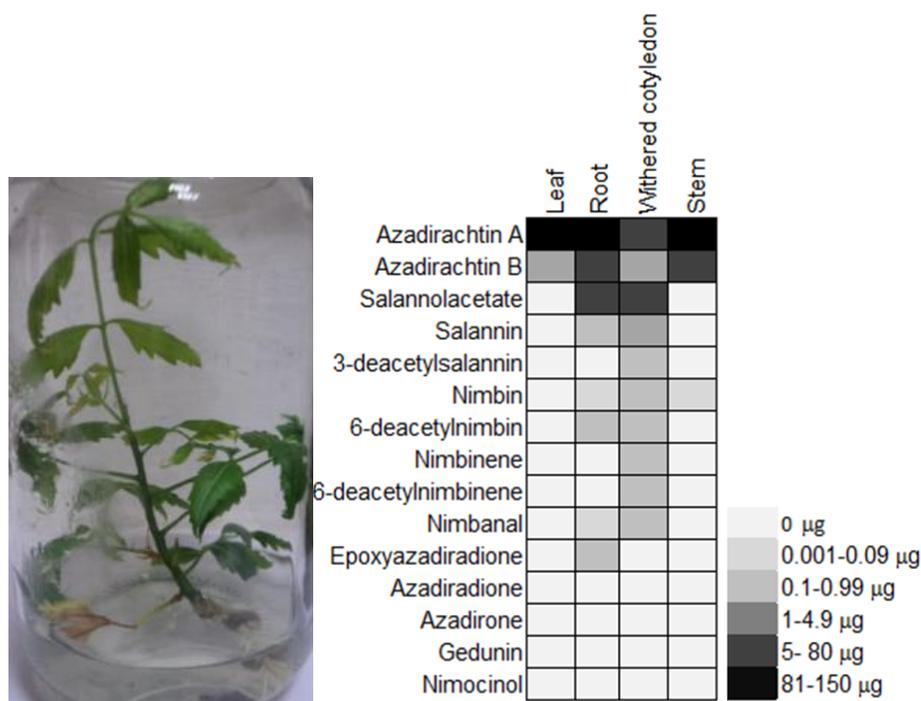

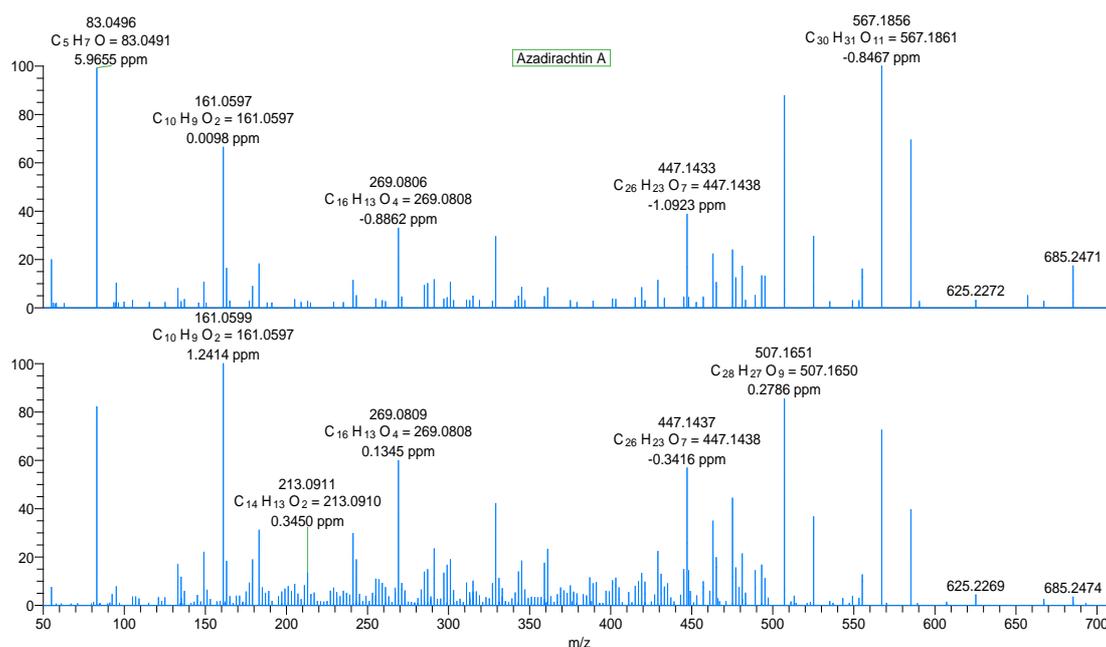

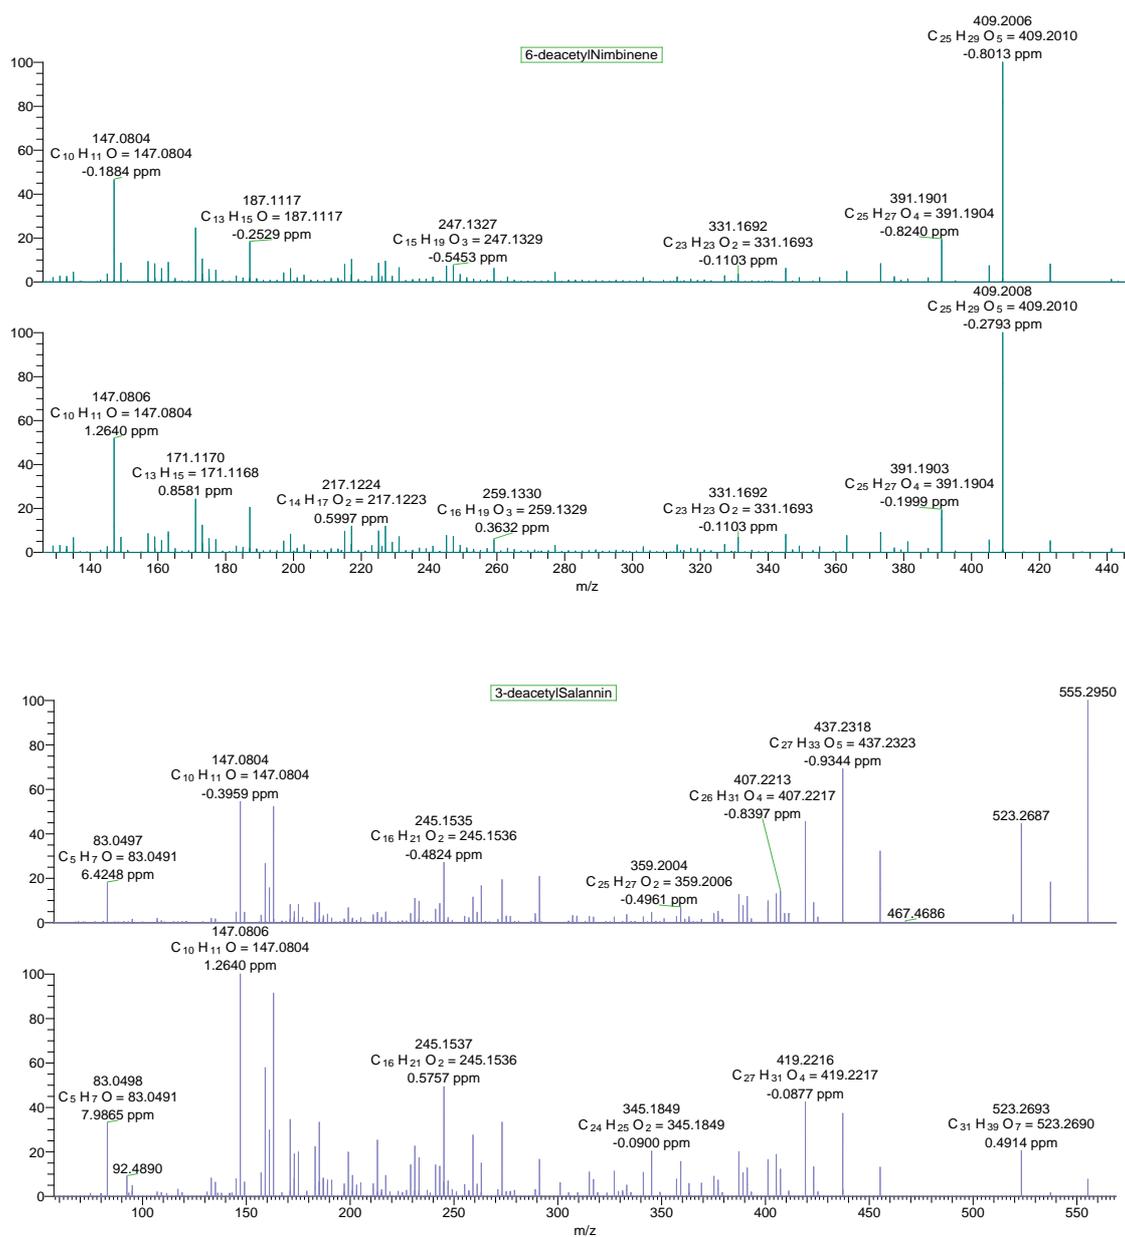

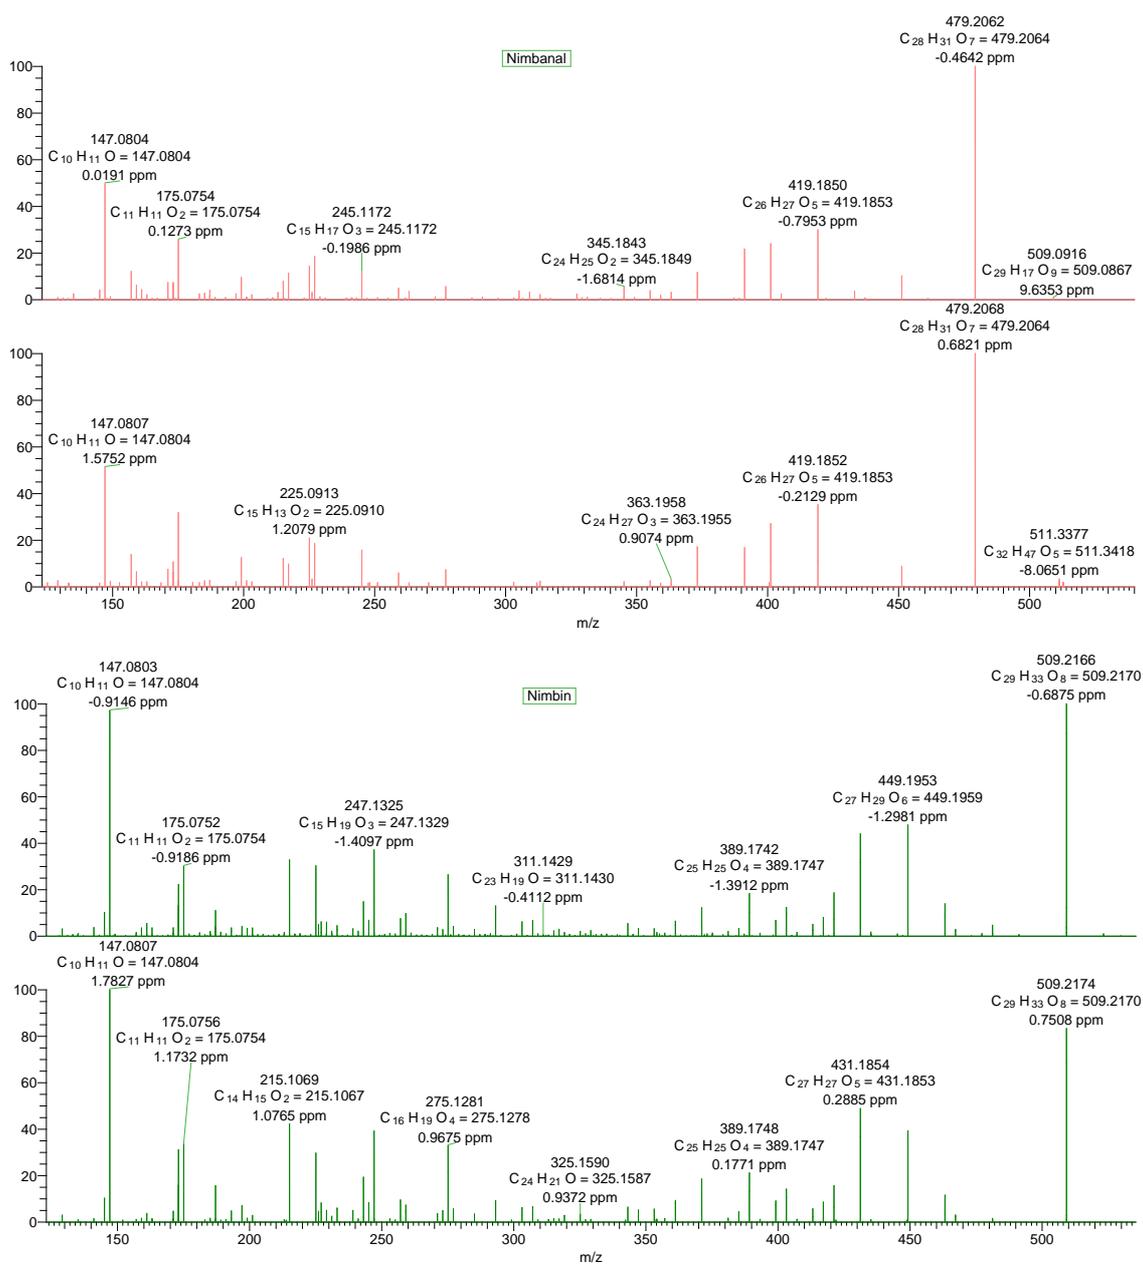

Figure 2A.7. Targeted limonoid profile (Right) of *in vitro* grown neem seedling emerged from cotyledons (Left).

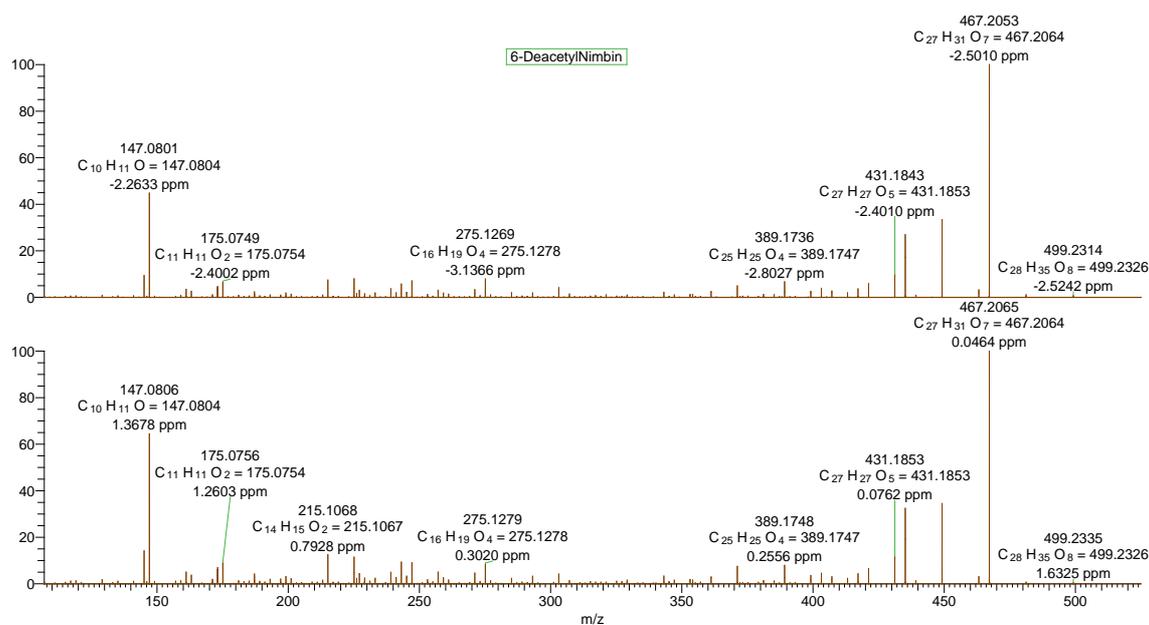

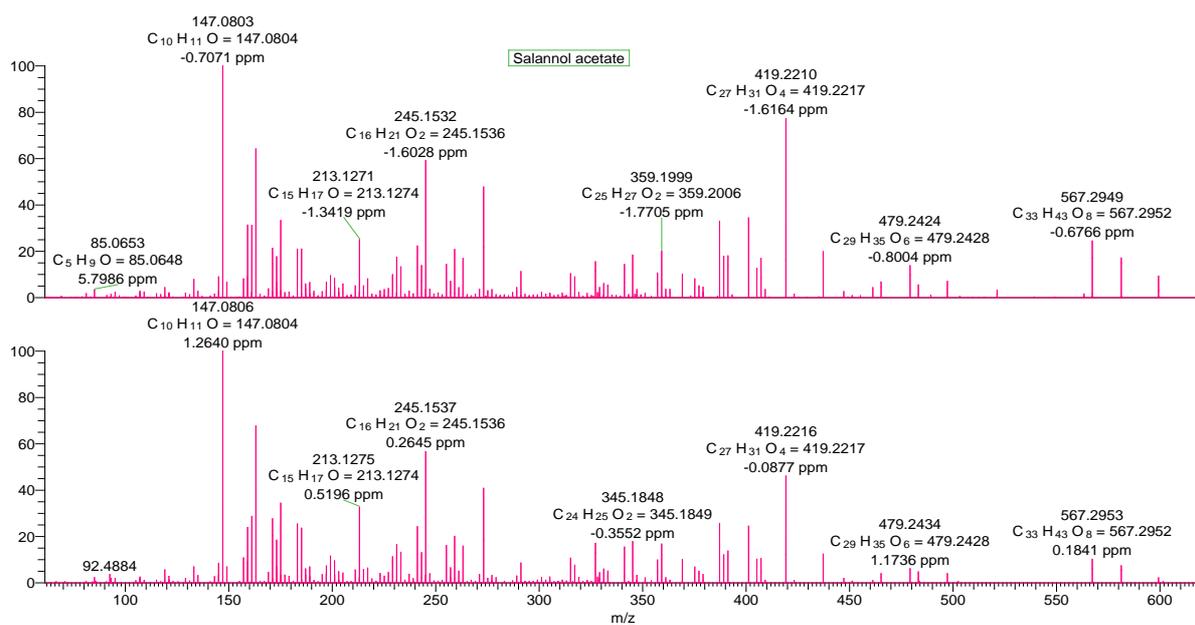

The studies indicated that both ring intact (basic) and C-seco limonoids were identified in the newly formed callus however, in subsequent subcultures, the levels of ring intact limonoids decreased gradually. At the end of three subcultures, the basic limonoids were not detected. C-seco limonoids such as azadirachtin A, salannin, salannolacetate, 3-deacetylsalannin, nimbin, 6-deacetylnimbin, nimbinene, 6-deacetylnimbinene, nimbanal were found in callus and suspension culture of neem cells as identified (Figure 2A.8) and quantified based on extracted ion chromatogram. Callus inoculum of 0.2 g, was dispersed in 5 mL of liquid MS media to initiate cell suspension culture, which showed a typical growth curve (Figure 2A.9B). A lag phase of 5 days was observed from the day of inoculation, followed by exponential phase for the next 5 days.

Following the exponential phase, linear growth phase was observed for 9 days and the stationary phase started from day 20. Nine limonoids identified in the suspension culture were quantified over the time course of cellular growth (Figure 2A.9A). Limonoid accumulation in cells was recorded highest in the stationary phase of growth. Among the nine C-seco limonoids identified, level of 6-deacetylnimbin and 6-deacetylnimbinene were higher ($17 \mu\text{g/g}$ and $8 \mu\text{g/g}$ of cells respectively) among the tetranor- and pentanor-triterpenoid group of limonoids, respectively in the cell suspension culture. In the media, the limonoids were identified in traces (Figure 2A.9). The traces of limonoids identified in the media may be from the ruptured cells formed during the generation of suspension from callus. These results show that limonoids are synthesized and stored inside the suspension cells.

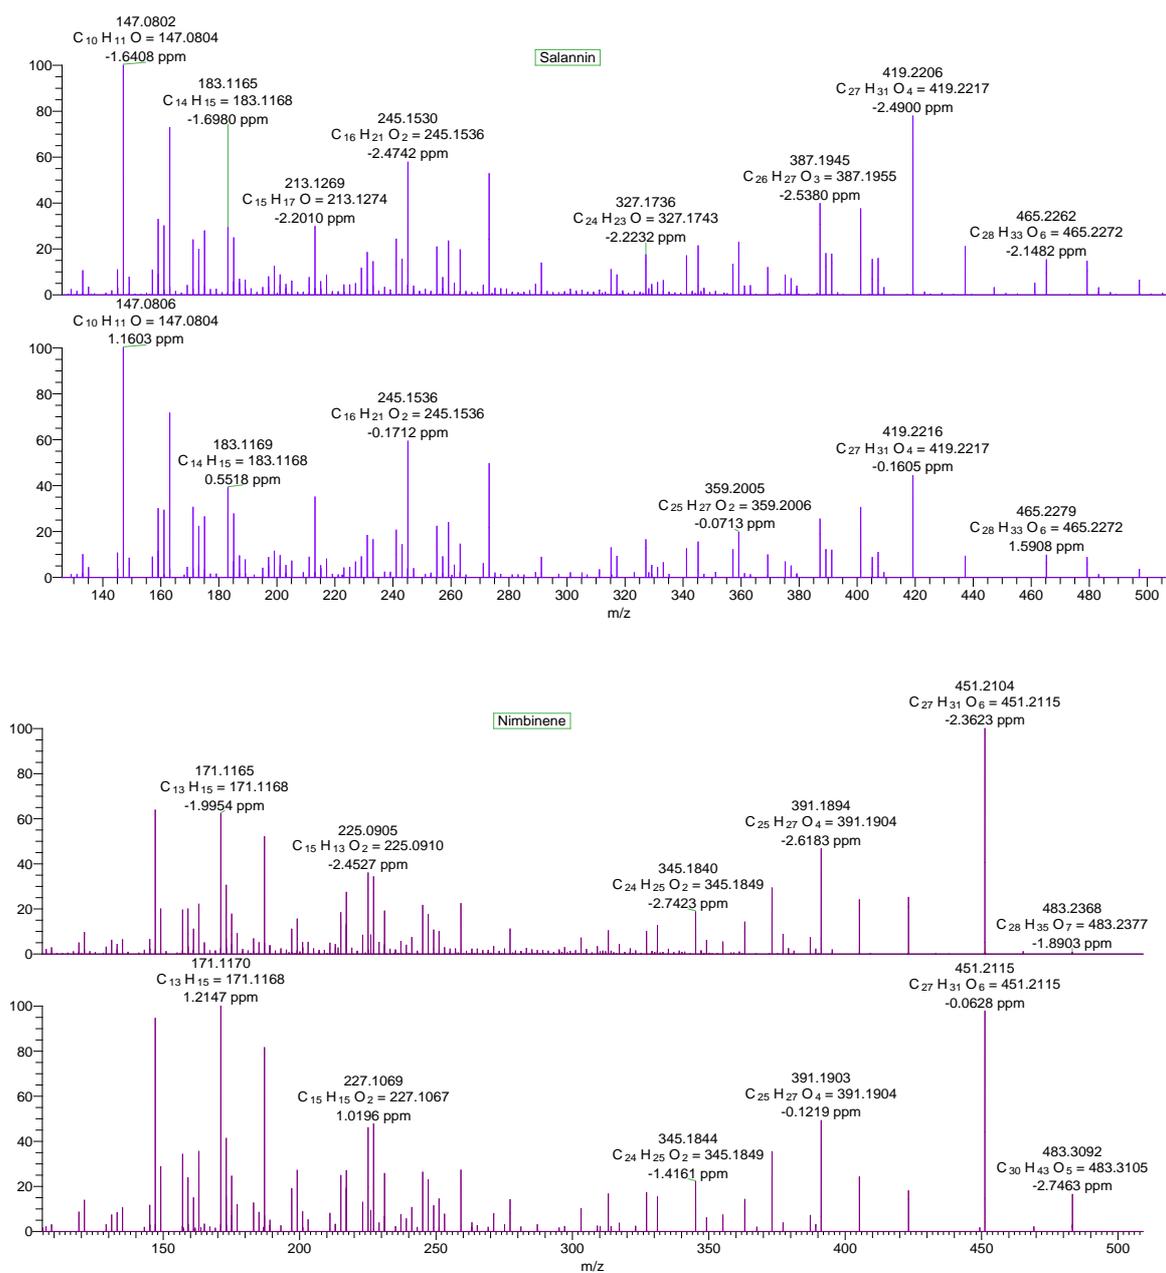

Figure 2A.8. Overlay of MS/MS spectra of 9 limonoids standards (bottom) and the limonoids biosynthesized from cell culture (top).

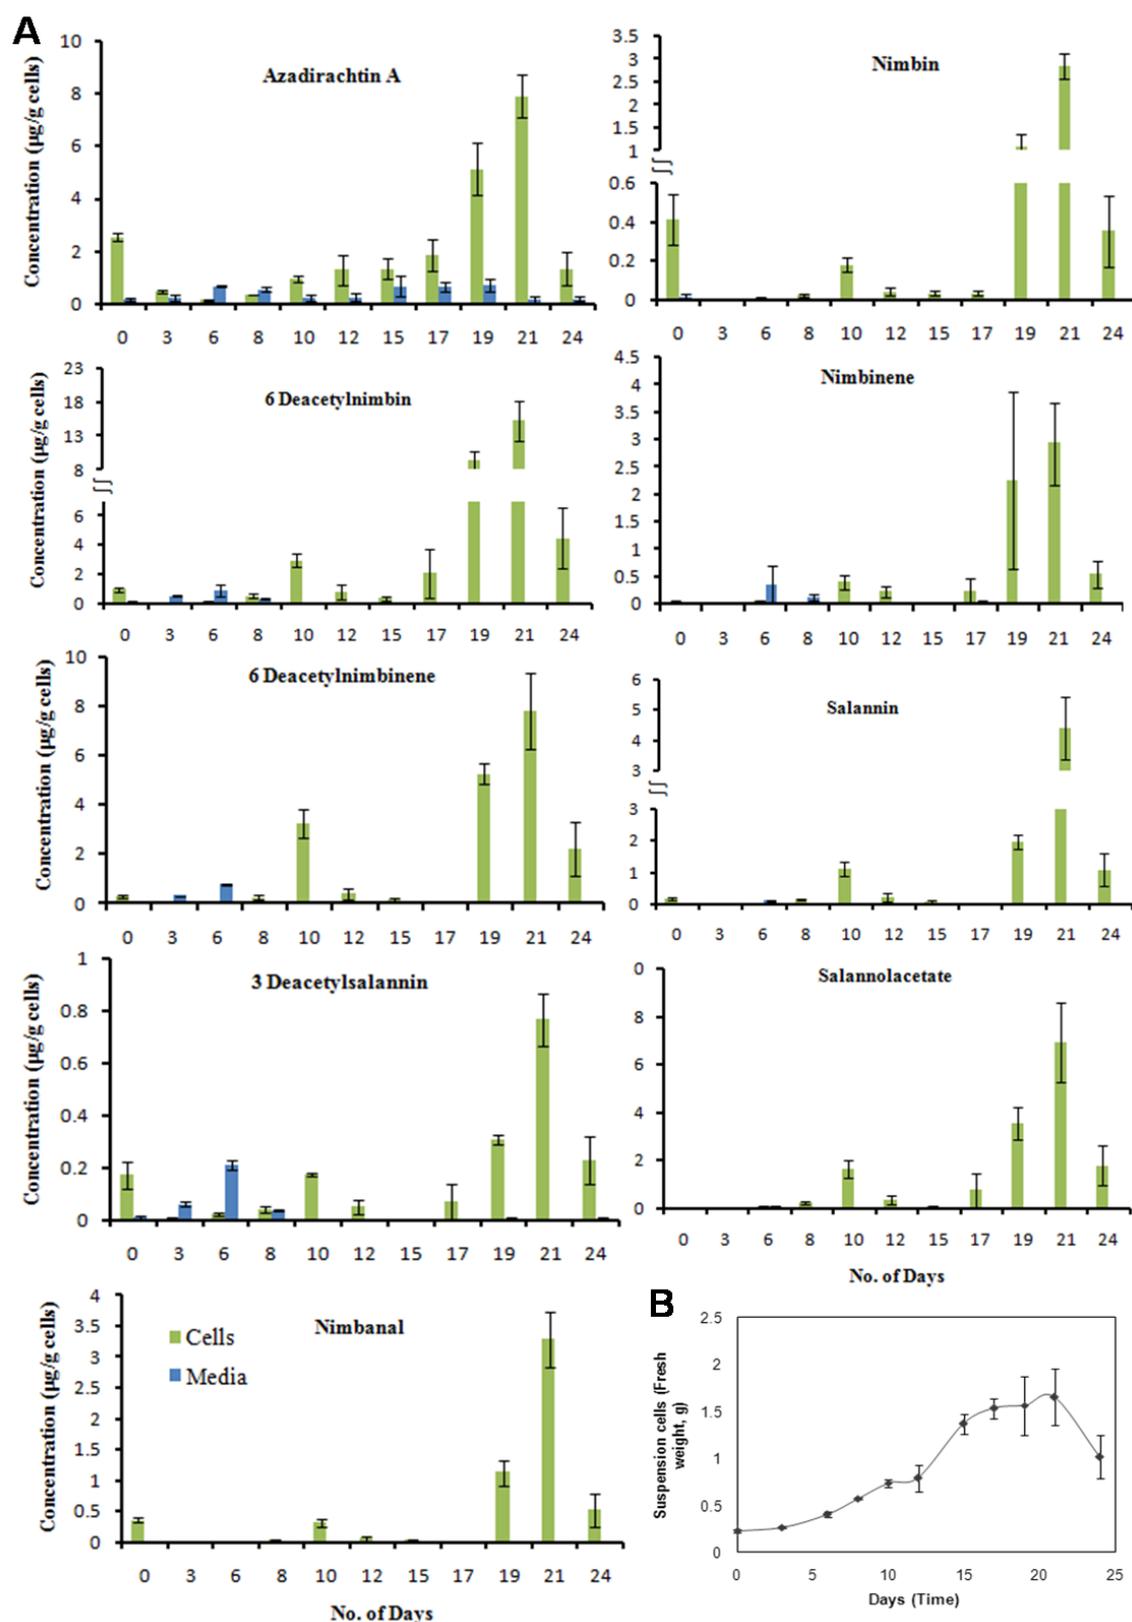

Figure 2A.9. Growth of suspension cells and time course study of limonoid biosynthesis. (A) limonoid content during the course of cellular growth. (B) Growth curve obtained with cell suspension.

The azadirachtin production from cell culture developed from different plant parts has been studied, aiming to maximize its productivity^{8, 22}. Our study gives insights into specific limonoid profile during growth and development of neem plant. The neem cotyledons inoculated over media has grown into a seedling, the withered cotyledon has lost its limonoid content and limonoids might have been distributed into the growing plant part during its development. This has been hypothesized based on the quantitative comparison of individual limonoid content of the different plant parts and found that azadirachtin A was highest in stem, followed by root and leaf during plant development. Limonoid profiling studies of *in vitro* plant and neem sapling leaves demonstrated the high level occurrence of C-seco limonoids, specifically azadirachtin A in similitude to the pattern of kernel tissue (Figure 2A.7), whereas the leaves of wild grown neem tree were known to contain ring intact limonoid, nimocinol as a major compound⁴. This growth specific differential limonoid profile can be explained in terms of chemical defense theory³³. The high levels of potent insect deterrent azadirachtin A can protect the young leaf, as soft tissues are more susceptible to herbivory. Whereas azadirachtin A content was less (700 fold less than nimocinol) in mature leaf. Similar observation on defense mechanism has been reported in tea leaves, where caffeine is found to accumulate in young leaves and its biosynthesis has been halted as the leaf ages and get cellulose and lignin deposits for its protection from predators³⁴.

Our present study indicates that undifferentiated, suspension cells and callus derived from kernel contain C-seco limonoids. C-seco limonoids are continued to be biosynthesized in subsequent subculturing (Figure 2A.8, 2A.9), and on the other hand shows the absence of ring intact limonoids. This follows the trend of limonoid content as that of its parent tissue, the fruit kernel however the occurrence of individual C-seco limonoids varies. Azadirachtin A was found to be the abundant C-seco limonoids in kernel whereas kernel derived cell lines contain 6-deacetylnimbin and 6-deacetylnimbinene in high levels (Figure. 2A.9).

2A.3. Conclusion

Callus and suspension culture were established from neem kernel inoculated in MS media with 2 mg/L NAA and 0.2 mg/L BAP. *in vitro* plantlets were obtained from cotyledons after 30 days of inoculation. Time course study for limonoid biosynthesis

showed that its accumulation was recorded high on the day 21 of the growth phase. 6-deacetylnimbin was the highly biosynthesized limonoid identified in the cell culture. 6-deacetylnimbin, azadirachtin A and salannolacetate are the major limonoids among the 9 limonoids identified in cell suspension. In the *in vitro* plantlets, azadirachtin A, B and salannolacetate were the major limonoids produced.

2A.4. Materials and methods

2A.4.1. Plant materials

For the initiation of cell culture, fruits in third to fourth developmental stages were collected from CSIR-NCL campus. Neem fruits at different developmental stages were collected during the month of April-June.

2A.4.2. Surface sterilization of neem fruits

Hard green neem (*Azadirachta indica*) fruits obtained from NCL campus was surface sterilized by rinsing in deionised water followed by incubation in 1% Bavistin supplemented with few drops of Tween-20 for two hours under shaking. It was then rinsed thrice in deionised water followed by washing in 70% ethanol for 30 sec. Then 1% sodium hypochlorite solution was used for surface sterilization for 7 min. The fruits were then rinsed thoroughly in sterile, deionised water several times.

2A.4.3. Development of callus from neem kernel

For formation of callus, kernels separated from hard seed coat or testa were aseptically transferred and inoculated over MS (Murashige and Skoog) basal media supplemented with 3% sucrose, 2 mg/l NAA and 0.2 mg/l BA at pH 5.8 and solidified with 0.25 % Phytigel™ in 66 mm × 59 mm magenta culture vessel. It was then incubated under the conditions of 600 lumens of light during 12 hours day/night cycle at 25 °C.

2A.4.4. Generation of cell suspension from callus

Azadirachta indica suspension cell cultures were initiated from cultured callus and maintained in liquid MS (Murashige and Skoog) basal media of same composition mentioned earlier and grown with rotatory gyration at 125 rpm at 25 °C in dark.

2A.4.5. Growth conditions for neem plantlets

Hard green neem (*Azadirachta indica*) fruits were surface sterilized and the cotyledons (kernel) were obtained from the fruit as mentioned earlier. The cotyledons were inoculated over MS (Murashige and Skoog) basal media with 0.25% Phytigel™ (Sigma) and incubated at 25 °C in a growth chamber (Percival Scientific) with a cycle of 16-h light/8-h darkness.

2A.4.6. Harvesting cells and Extraction of limonoids

The suspension culture cells were collected from media by centrifugation at 2500 × g for 10 min at 25 °C. The cells were homogenized in ice-cold methanol. The supernatant was collected after centrifugation at 2500 × g for 10 min at 25 °C. The cells were again resuspended in twice the volume of methanol and extracted twice again. The methanol extract was pooled together and evaporated to dryness. The residue was partitioned between water and ethylacetate thrice. The ethylacetate pool was then evaporated to dryness under reduced pressure and constituted with LC-MS grade methanol to the volume of 1 mL. To quantify limonoids in the media, it was partitioned with ethylacetate and extracted, as mentioned above.

2A.4.7. Limonoid profiling in callus and cell culture

Targeted metabolic profiling of callus at different subculturing stage of callus and cell suspension was carried out with LC-ESI-MS as described below by comparison with the 19 limonoid standards isolated and characterized from neem fruit and oil^{35, 36}. The identified limonoids were subjected to tandem MS to confirm their identity based on the presence or absence of the signature fragments as established in our previous study^{35, 36}.

2A.4.8. LC-ESI-Mass Spectrometry conditions

Analysis of neem limonoids was performed with Thermo Scientific QExactive™ hybrid quadrupole-Orbitrap mass spectrometer associated with Accela 1250 pump and Accela open AS. The conditions of HESI source include capillary temperature of 320 °C, Heater temperature at 350 °C, s-lens RF level of 50, Spray voltage of 3.6 kV, spray current of 0.9 μA with sheath gas flow rate of 41, Auxiliary gas flow rate of 9 and sweep

gas flow rate of 3. Standards, as well as the extracted samples, were analyzed in positive ionization mode, in full MS-scan with scan range of 100 to 1000 m/z . Following were the properties of the scan performed- resolution 70,000, AGC target $1e6$, Maximum IT 200 ms. Waters Acquity UPLC BEH C_{18} column (particle size 1.7 μm , 2.1 X 100 mm) was used as the stationary phase while the solvent system of methanol and water containing 0.1% formic acid served as the mobile phase. The gradient started with 40% methanol (5 min isocratic), it was then increased to 50% (5 min isocratic), followed by 60% methanol for the next 15 minutes and over the next 4 minutes it was isocratic with 65% methanol. It was then increased to 90% methanol for 4 minutes. For the last 2 minutes, it was isocratic with 40% methanol. Constant flow rate of 0.3 mL min^{-1} was maintained throughout the run time of 35 min. The chromatograms and mass spectral data were processed by Xcalibur qual browser (version 2.3; Thermo Scientific).

2A.4.9. Time course of cellular growth and limonoid formation

0.2 g of callus tissue was inoculated in liquid MS to generate suspension and the cells were harvested at 12 different time points. Fresh weight of cells at different time points were estimated and limonoids were extracted from cell mass at each time point. Based on the calibration curve of authentic standards, 9 limonoids were quantified by considering the peak area of extracted ion chromatogram (EIC) corresponding to the combined protonated and sodiated molecular ions⁴. From the *in vitro* plantlets, leaf, stem, root and withered cotyledon were collected and quantification of limonoids was performed as mentioned above.

Chapter 2: Section B
**Study of localization of neem metabolites in
different tissues**

2B.1. Introduction

In the process of co-evolutionary arms race between plants and the biotic or abiotic environment it interacts, each plant species have carved a niche for itself by evolving specialized metabolism due to its specific ecological challenge and is therefore unique to each plant species and is not shared by other plant family³⁷. Myriads of plant specialized metabolites in aggregate has evolved in plants as an arsenal of defense because of adaptive selection of the new response of other organisms results in further selection in plants for higher fitness. These evolution occurs not only with the synthesis of new metabolite but also with the specialized cell types specifically enriched with specialized molecular machinery for the synthesis, transportation and storage of these metabolites³⁸.

Anatomical clues in plants that have sequestered lots of active compounds are

- Glandular trichomes,
- Laticifers and idioblasts
- Secretory cavities
- Resin canals
- Floral & extrafloral nectaries.

Plants are capable of producing remarkable variety of metabolites in terms of chemical complexity and diversity that shows differential spatial distribution in tissues³⁹,⁴⁰. For immense biosynthesis of specialized metabolites and their sequestration, plants have evolved specialized anatomical appendages and cell types such as trichomes, idioblast cells, laticifers, resin cells, secretory cells, gland or cavities⁴¹⁻⁴³. These structures help plants for the efficient utilization of secondary metabolites for defense or pollinator attraction and also to protect the adverse and detrimental effect for the producing plant⁴⁴⁻⁵¹. Site of synthesis and localization of a different class of secondary metabolites in plants varies and shows a higher extent of compartmentation. Glandular trichomes have been known remarkably for the synthesis of a different class of terpenes, essential oils and other secondary metabolites in plants^{42,52-54}. For example, sesquiterpene lactones uvedalin and enhydrin have been found to be localized into glandular trichomes in leaf⁵⁵. Essential oils in Eucalyptus are stored in sub-dermal secretory cavities⁵⁶. Similarly, secretory cells present in the trichomes of peppermint were found to synthesis and store monoterpenes⁵⁷. This metabolite production capacity

of trichomes is not only attributed to high expression level of the pathway genes but also due to the photosynthetic efficiency for generating energy, carbon and reducing power etc which acts as substrate and cofactors for enzymes respectively.⁵⁸. The intracellular site of synthesis, translocation, localization of terpene indole alkaloids and tropane alkaloids in *Catharanthus* and opium poppy respectively in different cell types such as laticifers and idioblasts has been significantly revealed⁵⁹⁻⁶⁴.

Apart from the specialized cells, vacuoles and vesicles are important intracellular organelles, which are known to accumulate secondary metabolites thereby aiding in prevention of self-toxicity for the host cells⁶⁵. Synthesis of a complex secondary metabolite requires multiple organelles such as chloroplast, cytosol, endoplasmic reticulum, vesicles, vacuoles and nucleus. In addition to the specific localization of alkaloids in vacuoles of *Catharanthus*⁶⁶, alkaloids are also found to exist as a complex with tannins showing vacuolar compartmentation⁶⁷. Another notable intracellular compartment existing in plants is oil body, found predominantly in seed but it also occur in other parts⁴¹. Oil body also called as oleosomes, is a sphere of triacylglycerol bounded by a phospholipids monolayer with basic proteins oleosins embedded in it, conferring stability^{41, 68, 69}. It serves as food reserves for germination and post-germinative growth of the seedlings by resisting the physical stresses caused during germination and desiccation⁴¹. Oil bodies of few plants and liverworts are also found to biosynthesize and accumulate terpenoids as evidenced from the localization of enzymes and metabolites in it⁷⁰⁻⁷². The secretory structures are considered as natural cell factories and are becoming important targets for metabolic engineering⁷³.

For example, the study of *Catharanthus roseus* terpene indole alkaloid biosynthesis showed that five intracellular compartments such as chloroplast, vacuole, nucleus, endoplasmic reticulum and cytosol, four different cell types such as epidermis, internal phloem-associated parenchyma, laticifers and idioblasts are involved at various steps. Such studies have also implicated many issues namely, localization and expression of pathway enzymes, mechanisms of intra- and intercellular trafficking of intermediates, cloning and functional characterization of genes coding for pathway enzymes, mechanism of regulation of pathway by transcription factors, control of relative diversion of metabolite flux at crucial branch points and ultimately, improving metabolic engineering approaches^{43,57, 74, 75}. Thus, these sub-cellular compartments serve

as an efficient storage site for the biosynthesis and storage of secondary metabolite which helps in defense of the plants from various biotic and abiotic factors.

In our laboratory, we have identified previously, the tissue and developmental stages specific differential distribution and abundance of ring intact (basic) and C-seco limonoids in different neem tissues⁴. This incredible and impressive abundance of limonoids in fruit and leaf tissues actuated us to look for the specialized cells involved in accumulating limonoids and other metabolites. Numerous resin glands on the surface of neem leaves, secreting resin, accumulates flavonoids, and have been identified already^{76, 77}. Here, in our present investigation, we discuss about the cellular and sub-cellular structures involved in the storage of limonoids, flavonoids, sesquiterpenes and hydrocarbons in neem.

Purpose of the present study is to provide new elements on morphology, localization of limonoids and other metabolites in each of the specialized structures and also to elucidate the role of them in interaction with biotic factors such as insects. As a first step to determine the structures involved in the biosynthesis and storage of limonoids, we studied the histology and histochemistry of fruit, leaf and flower. Idioblasts, the specialized cells involved in localization of secondary metabolites were evident from its natural pigmentation. Further, the lipophilic components of the cells were unveiled through histochemical analysis. Moreover, the protoplast, cell homogenate and organelle purifications were carried out followed by targeted and untargeted metabolic profiling of the isolated cells and organelles using HRMS as a strategy to elucidate the localization of limonoids and other metabolites in their respective cells and intracellular compartments. Thus the presence of morphological elements such as trichomes, laticifers, pollen, idioblasts, vacuoles, vesicles, oil bodies, cytoplasmic droplets meant for different functions were deciphered through our study. Furthermore, the herbivory deterrence of the latex has been confirmed based on the studies on insect, *Helicoverpa armigera*. Though the anti-feedant, insect growth regulatory, anti-insecticidal properties of several limonoids have been investigated through several studies⁷⁸⁻⁸⁵, and on different insects, the effect of neem fruit latex, the cytosol of laticifer cells have not been examined so far. Hence, effect of neem latex on insect feeding and survival is examined through this study.

2B.2. Results and discussion

2B.2.1. Identification of limonoids in neem fruit latex

One of the distinctive ways of defense for plants against predators is mediated through endogenous fluid, latex stored in the highly specialized laticifer cells, which is known to harbor bioactive secondary metabolites⁸⁶ and has been found to be present in plant parts such as stem, fruits, leaves etc. in different plant system⁸⁶. Neem is very well known for its effective and diverse biological activities. Despite the wide knowledge on the chemistry and medicinal property of neem, localization of these medicinally active metabolites in specialized cells and structures of the plant has not been examined heretofore. Although, several biologically active limonoids have been isolated from various neem tissues, no information is available on the limonoid content of milky latex of neem fruit. In order to identify the limonoid content of neem latex, the crude extract was subjected to Thin Layer Chromatography (TLC) analysis (Figure 2B.1). Neem limonoids such as azadiradione, epoxyazadiradione, azadirone and other triterpenes such as α -amyrin, β -amyrin, lupeol and Euphorbia *tirucalli* isolates tirucallol and euphol were used as standards. From the TLC analysis, azadiradione, epoxyazadiradione and azadirone were found to be the major limonoids. UPLC-ESI (+)-MS/MS characterization was further done to identify the limonoids present in trace amounts (as mentioned in materials and methods)⁴. Analysis of total ion chromatogram (TIC) and mass spectra indicated the presence of over thirty limonoids (Appendix Figure 2B.1, Table 2B.1). Seventeen of them were identified based on the comparison of retention time and m/z value respectively, with that of authentic standards isolated and characterized from neem^{35, 36} (Table 2B.1). The limonoids were then confirmed for its identity by subjecting it to MS/MS of different normalized collision energies (NCEs) and m/z values of signature fragments engendered were matched with already available m/z signatures generated from authentic limonoid standards^{35, 36}. For the identification of limonoids for which standard was not available, elemental composition was generated in Xcalibur qual browser for the individual m/z values and molecular formula was assigned putatively. These limonoids were further confirmed by comparing signature MS/MS fragments obtained at standardized NCE of 20% and 25% for C-seco limonoids and ring intact limonoids, respectively (Appendix Figure 2B.1, Table 2B.1). Further, relative abundance of individual limonoids in latex was calculated (Figure 2B.3) based on the

peak area obtained from the extracted ion chromatogram generated from the m/z for the corresponding limonoids. Absolute quantification was carried out for the fifteen limonoids with authentic standards based on the standard curve drawn for each of them by considering both protonated molecule as well as sodium adduct ions⁴ (Table 2B.1). The basic limonoid, azadiradione was found to be the major constituent in the latex, followed by epoxyazadiradone and gedunin whereas complex, highly modified C-seco limonoids such as nimbin, salannin, azadirachtin and its derivatives were identified in traces (Figure 2B.3, Table 2B.1). The concentration of azadiradione and epoxyazadiradone present in the latex was found to be 3.2 and 2.4 mg mL⁻¹, respectively. Thus, limonoid profile of latex suggests that ring intact (basic) limonoids such as azadiradione and epoxyazadiradone represents the metabolic fingerprint of neem fruit laticifer cells. Neem latex profile reveals high abundance of ring intact limonoids, azadiradione and epoxyazadiradone, which underpins our hypothesis that it, is one of the intermediate in limonoid biosynthetic pathway. The early step intermediate, azadiradione accumulates in higher amount and azadirachtin, a complex, final step limonoid is being present in trace amount in the latex obtained from neem fruit stage 3. This is in contrast to the composition of latex from laticifer of poppy (*Papaver somniferum*) and *Catharanthus roseus* that were found to accumulate the final step metabolite and late step intermediate, morphine⁶³ and demetoxyvindoline respectively, the products of alkaloid biosynthetic pathway in latex^{62, 86}.

Table 2B.1. Limonoids identified in the neem latex based on the comparison of retention time with the standards and also from the presence of signature fragments unique for the specific class of limonoids obtained from tandem MS analysis ('-' denotes that absolute quantification has not been carried out).

2B.2.2. Ultrastructure and histochemistry of latex

Since, latex was found to be a rich source of limonoids, we were curious to look for its morphology and ultrastructure. Preliminary investigation of the latex under light microscope showed the presence of abundant spherical vesicles (Figure 2B.3B, 2B.3D). The vesicular nature of the spherical bodies was further confirmed using environmental Scanning Electron Microscopy (eSEM) and size of them were 6 - 15 μm in diameter having smooth surface morphology (Figure 2B.3C). It also manifested the presence of particles, named as type I and II for easier understanding. Type I particles ranged from 1 - 3 μm diameter and type II particles were abundant in number and are less than 1 μm in size (Figure 2B.3C, 2B.3G). To further identify the nature of vesicles, histochemical analysis was performed in which we stained the diluted latex with different dyes. The optical light microscopic examination of cytoplasmic vesicles treated with the dye, Oil Red O stained them red showing their lipophilic nature (Figure 2B.3E), which was further confirmed, more specifically, by confocal microscopy of the vesicles stained with Nile Red. The Nile Red stained vesicles, fluoresce magenta at 648 to 698 nm emission (Figure 2B.3F), indicating the presence of polar lipids in the vesicle membrane but not the neutral lipids as it seldom generated green fluorescence at 525 to 567 nm

emission collected. However, chemical composition of them is still undiscovered as separation of these components is challenging.

The multitude of cytoplasmic vesicles present in the neem fruit latex are relatively largest when compared to the ones identified so far in the latex of other plant systems such as *C. roseus*⁸⁷ and opium poppy⁸⁸. Role of these cytoplasmic vesicles towards limonoid biosynthesis has not yet been elucidated and needs to be studied further. Apart from these vesicles, the most prominent component of the latex is the particles, which in para rubber tree (*Hevea brasiliensis*) and *Euphorbia* species latex were found to play essential role in accompanying the secondary metabolites^{89,90}.

(G) transmission electron micrograph of diluted latex showing type II particle, Bar = 0.2 μm

2B.2.3. The cellular and sub-cellular compartmentation of limonoids in fruit pericarp

The specialized cells also called idioblasts, involved in the sequestration of limonoids remain rarely investigated in neem⁹¹. To understand about the structure and organization of specialized cells in the fruit pericarp, we examined the sections of fruit, generated using vibratome by light microscopy. The transverse section of the third developmental stage fruit gave rise to sections of small kernel surrounded by pericarp (Kernel at the centre has been separated, Figure 2B.4A). The optical light microscopic examination of pericarp revealed the presence of laticifer cells, the site of localization of white latex in the fruit (Figure 2B.4B and 2B.4A). The length of the laticifer cells was found along the longitudinal axis of pericarp. Epicarp of the fruit was deprived of laticifers and they were intense in the mesocarp and endocarp regions (Figure 2B.4A). In addition to laticifers, the longitudinal (Figure 2B.4G) section of pericarp (Figure 2B.4B, 2B.4D and 2B.4E), showed the presence of idioblast cells, which were naturally colored, dark reddish brown in hue and were concentrated near the laticifer cells. It varied in size from 20 - 70 μm in diameter. Fused tricarpeles of the fruit, as evidenced from the cross section of third developmental stage of fruit (Figure 2B.4A) also showed the presence of idioblast cells (Figure 2B.4D and 2B.4E).

Further, to study the limonoid profile of pericarp cells devoid of latex, of pericarp tissue was treated with cell wall digestive enzymes, which yielded dissociated cells (Figure 2B.4C). These cells exhibited the presence of prominent vacuoles. Limonoid profiling of this dissociated pericarp cells showed that azadiradione and epoxyazadiradione are the major constituents, in this tissue (Figure 2B.4I). Abundant idioblast vacuoles from the pericarp tissue of the fruit were obtained which was characterized for its morphology using light microscopy (Figure 2B.4F). The pericarp idioblast vacuoles characterized by eSEM showed hemispherical morphology, ranging from 3 - 7 μm diameter (Figure 2B.4J). Azadiradione and epoxyazadiradione obtained

from the idioblast vacuoles were found to be 5.8 and 2.5 mg/g of tissue, respectively. Remarkably, limonoid levels of the pericarp idioblast vacuoles along with the amount from latex were in agreement with the limonoid content of the pericarp tissue (Figure 2B.4H). The individual limonoid profile of latex, and pericarp cells showed a limonoid distribution pattern that is paradigm of the pericarp limonoid profile⁴ and from this study, we could infer that azadiradione and epoxyazadiradione present in fruit are the most abundant limonoids in the neem tree.

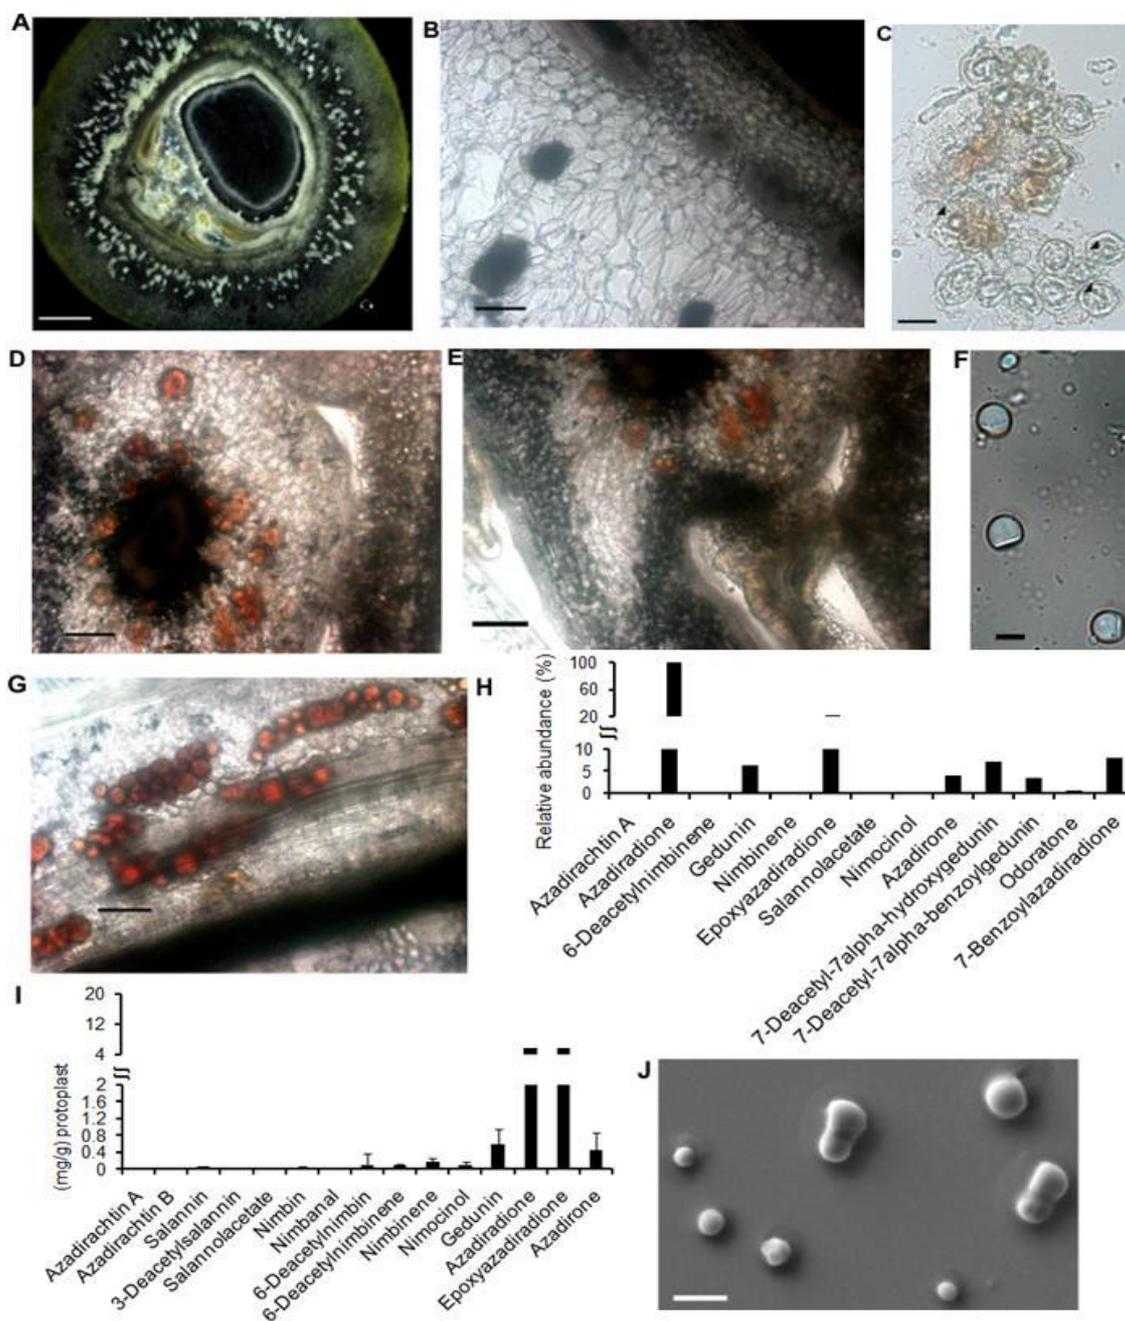

Figure 2B.4. Distribution of idioblast cells and laticifers in fruit pericarp. 2B.2.4. The evidence for intracellular localization of limonoids in kernel

In order to identify the compartmentation existing for localization of limonoids in kernel, histochemical studies of kernel was carried out. The kernel section (30 micron thickness obtained) was stained with toluidine blue evidenced the presence of idioblasts cells in the kernel section as idioblasts took magenta coloration, differentiating them from the other cells (Figure 2B.5E). Nile red stained kernel section showed the presence of oil bodies of variable size range present in the different cells (Figure 2B.5I). Light microscopic examination of the epidermal region of kernel section demonstrated the presence of single prominent oil body in each cell, which ranged in size from 3 - 15 μm (Stained with Nile Red dye for discrimination, Figure 2B.5A). Epi-fluorescent microscopic observation showed red and green fluorescence from the oil bodies present in epidermis (Figure 2B.5K).

In order to understand the limonoid content of different cell types, protoplast preparation from different tissues were carried out. Kernel protoplast generated two types of population, the larger size ones (population I) being more than 100 μm in diameter harboring numerous oil bodies found as floating layer (Figure 2B.5B) and the smaller size protoplast (population II) pelleted at the bottom, less than or equal to 50 μm diameter, with the oil bodies being present in it (Figure 2B.5D). However, size of the protoplasts formed was found to be larger in the kernel of the fully matured fruit (Figure 2B.5C). The floating protoplast population was exhibiting green pigmentation whereas the pelleted population was of white coloration. The protoplast population I is enriched with high level of azadirachtin A and other limonoids being present in a meager amount, whereas population II demonstrated a modest amount of limonoids when compared to population I (Figure 2B.5F).

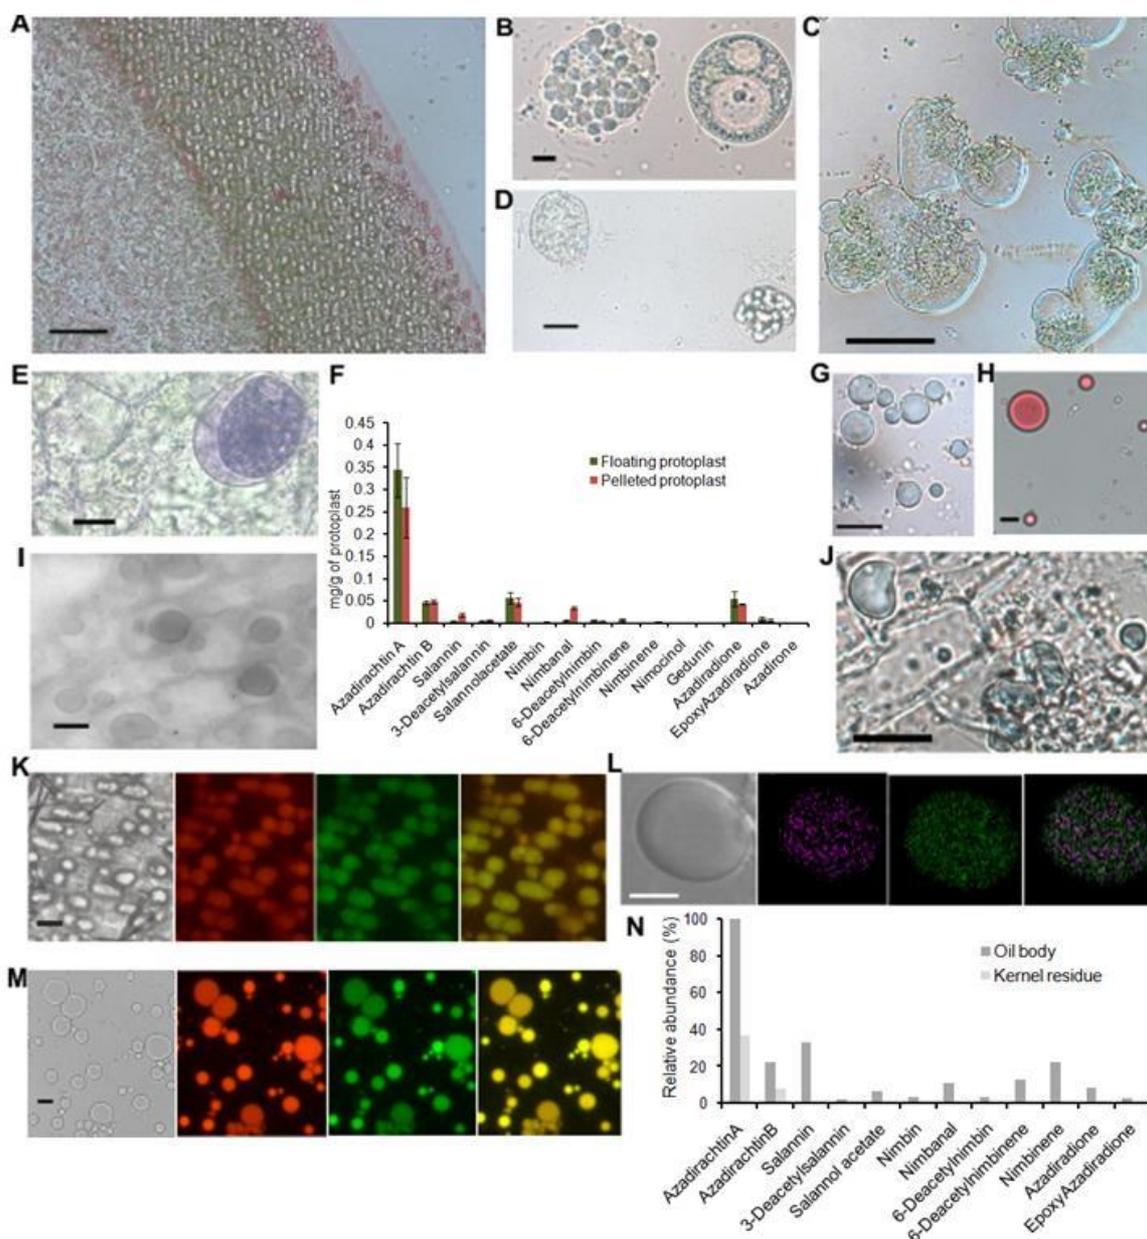

Figure 2B.5. Intracellular compartmentation in fruit kernel (A) kernel stained with Nile Red dye for discrimination of oil bodies in the epidermis, Bar = 50 μm . (B) floating protoplast population of kernel, Bar = 10 μm . (C) floating protoplast obtained from 4th developmental stage kernel Bar = 20 μm . (D) pelleted protoplast population of kernel, Bar = 20 μm . (E) kernel stained with toluidine blue distinguishing the idioblast cell, Bar = 10 μm . (F) limonoid profile of kernel protoplast population. (G) micrograph of kernel oil bodies, Bar = 10 μm . (H) isolated oil bodies stained with the dye Oil Red O, Bar = 10 μm . (I) light micrograph of kernel section stained with Nile Red, Bar = 20 μm . (J) Kernel residues showing vacuoles, Bar = 10 μm . (K) Epi-fluorescent micrograph of Nile Red stained kernel epidermis showing oil bodies, Bar = 10 μm . (L) confocal microscopy image of the isolated oil bodies from kernel, Bar = 5 μm . (M) Epi-fluorescent micrograph of the isolated oil bodies from kernel, Bar = 10 μm . (N) limonoid profile of kernel oil bodies.

To explore the chemical composition of oil bodies, isolation of it was carried using differential centrifugation, which is obtained as floating layer. When the oil bodies were isolated completely from the kernel (Figure 2B.5G), the kernel residue revealed the presence of vacuoles (Figure 2B.5J). Discrimination of vacuoles from the oil bodies was based upon non-uptake of lipophilic dyes and also, it had a distinct shape unlike that of oil bodies, which possessed vesicular nature. The lipophilic nature of the isolated oil bodies was evidenced again from its uptake of Oil Red O dye (Figure 2B.5H). Confocal microscopic studies of the isolated oil bodies stained with Nile Red dye, confirmed the presence of both polar and neutral lipids in it based on its magenta and green fluorescence, respectively obtained at two different emissions wavelengths as described earlier (Figure 2B.5L). Nile Red stained oil bodies in epi-fluorescence microscopy, showed both red and green fluorescence but the intensity were comparatively high in the small sized oil bodies less than 10 μm diameter (Figure 2B.5M). Comparison of total limonoid content of oil bodies and kernel residue harboring vacuoles depicted that oil bodies act as a major contributor of kernel limonoids (Figure 2B.5N) and the limonoids found in the kernel residue may be possibly contributed from the vacuoles (Figure 2B.5J). The oil body idioblast in kernel tissue harboring C-seco limonoids has been characterized from our studies.

Thus, the oil bodies present exclusively in kernel, represent vital feature for compartmentation in neem, which were more prominent in the epidermal cells and smaller in the cells of other regions of kernel tissue, and limonoids were accumulated in them predominantly. Oil bodies are suggested to be formed by budding out of cytoplasm oriented hemimembrane of endoplasmic reticulum membrane following the incorporation of neutral lipids such as triglycerides⁹². The contribution of oil bodies towards the storage of the invaluable insecticidal limonoid, azadirachtin A is revealed through the study of limonoid profile of isolated oil bodies and the oil body harboring floating protoplast population. Moreover, the morphology of oil bodies differed from that of the vesicles present in the latex. The oil bodies coalesce often and forms a floating layer in high-density solutions whereas, such density mediated separation was not observed with the cytoplasmic vesicles of the latex. Oil bodies acting as a site for intracellular accumulation of limonoids enables the plant cell for the compartmentation

of the water insoluble limonoid containing lipophilic domain from rest of the cytosol. This kind of co-occurrence of terpenoids in oil bodies has been reported previously in *Coleus forskohlii* root cork cells for the diterpenoid, forskolin⁹³. Comparably, the metabolism of isoprenoids have been reported in the *Marchantia polymorpha* thalli oil bodies⁷⁰, whereas *Arabidopsis* leaf oil bodies produce a phytoalexin under a pathological condition and an enzyme involved in sterol biosynthesis was also found to be localized in the lipid particles^{72, 94}. Oil cells in lemon grass leaves is also found to accumulate higher amounts of monoterpenes, citral⁹⁵ and similarly cinnamaldehyde in oil cells of *C. cassia*⁹⁶. These oil cells are lignified to protect the surrounding cells from the toxic effect of metabolite. To our knowledge, this study gives first evidence for the kernel oil bodies acting as the subcellular factories for the triterpenoids. Based on the limonoid profile of oil bodies and kernel residue containing vacuole, we hypothesize that, azadirachtin, the final product of limonoid biosynthetic pathway may be biosynthesized in the oil bodies and are transported to vacuoles through membrane fusion for sequestration in vacuoles, as proved for berberine synthesis for alkaloid compartmentation in *Berberis* species, according to a previous study where vesicles are considered to fuse with the vacuoles to release its contents^{97, 98}.

2B.2.5. Morphological characterization of suspension cells

Since each tissue was found to be specialized with cellular or sub-cellular compartments for limonoid localization, we studied undifferentiated suspension cells. These cells were derived from callus formed from the kernel tissue. For microscopic studies, suspension cells were generated from callus of different sub-culturing stages. Cells showed the presence of numerous granules in the cytoplasm when obtained from the initial sub-culturing stage (stage three) of callus (Figure 2B.6A). The number of granules in the cell was dwindling in the subsequent subculturing and at the end of two years of maintenance, (22 subcultures) most of the cells were either devoid of granules, or with few small granules (Figure 2B.6C). The morphology of the cell was recorded through eSEM (Figure 2B.6B). To study further, composition of the suspension cells, histochemical staining studies were carried out. Upon lugol's iodine staining, violet coloration was observed on these granules, which shows that they may play a role in starch storage (Figure 2B.6D). The investigation of suspension cells with lipophilic

stains such as Oil Red O and Nile Red showed absence of staining, which in fact suggests the absence of lipophilic oil bodies as that of kernel, the parent tissue.

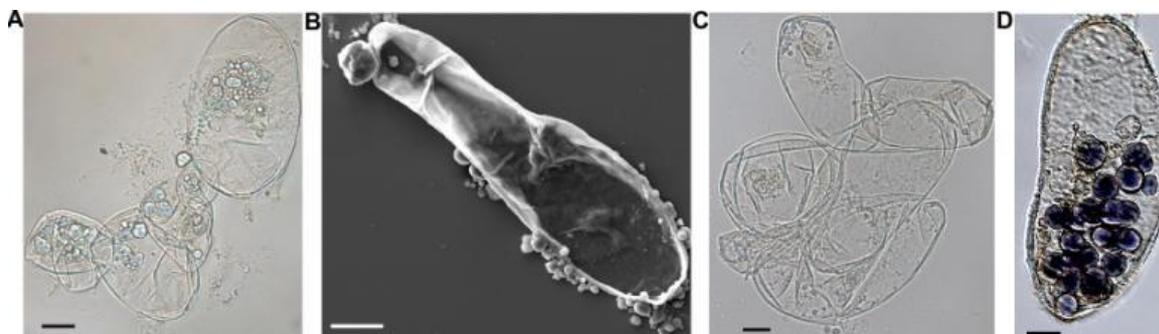

Figure 2B.6. Morphological characterization of *in vitro* cultured, undifferentiated cells (A) Cells of suspension derived from callus of third subculturing stage, Bar = 20 μm . (C) cells of suspension derived from callus maintained for one and a half years, Bar = 20 μm . (B) Scanning electron micrograph of a cell from suspension culture derived from callus of third subculturing stage, Bar = 20 μm . (D) same suspension cells stained with lugol's Iodine, Bar = 10 μm .

2B.2.6. Anatomical features of leaves associated with specialized cells and organelles

The cross section of neem leaf evinced the presence of distinct cells (idioblasts) interspersed among the mesophyll cells in the leaf blade, characterized by brownish yellow color (Figure 2B.7A). The size of the leaf idioblasts ranged from 18- 22 μm in diameter. Furthermore, in order to evidence idioblasts and the intracellular organelles in the leaf, the tissue was subjected to homogenization (Figure 2B.7C) and protoplast isolation separately which when examined through light microscopy, evidenced the individual idioblasts filled with numerous idioblast vacuoles (Figure 2B.7B). To further study the subcellular compartments involved in the intracellular localization of limonoids, the organelles were isolated from the tissue and limonoids were characterized from it. We carried out protoplast isolation from leaves of the *in vitro* grown neem plants, which manifested the aggregation of white particles at the top of the green protoplast pellet that was found to be idioblast vacuoles as evidenced through light micrograph (Figure 2B.7D). The white particles were characterized using eSEM that ranged in size from 0.5 – 3 μm diameter (Figure 2B.7F). Limonoid profile of these

idioblast vacuoles signified the presence of limonoids with the typical pattern of limonoid present in the *in vitro* leaf tissue (Figure 2B.7E).

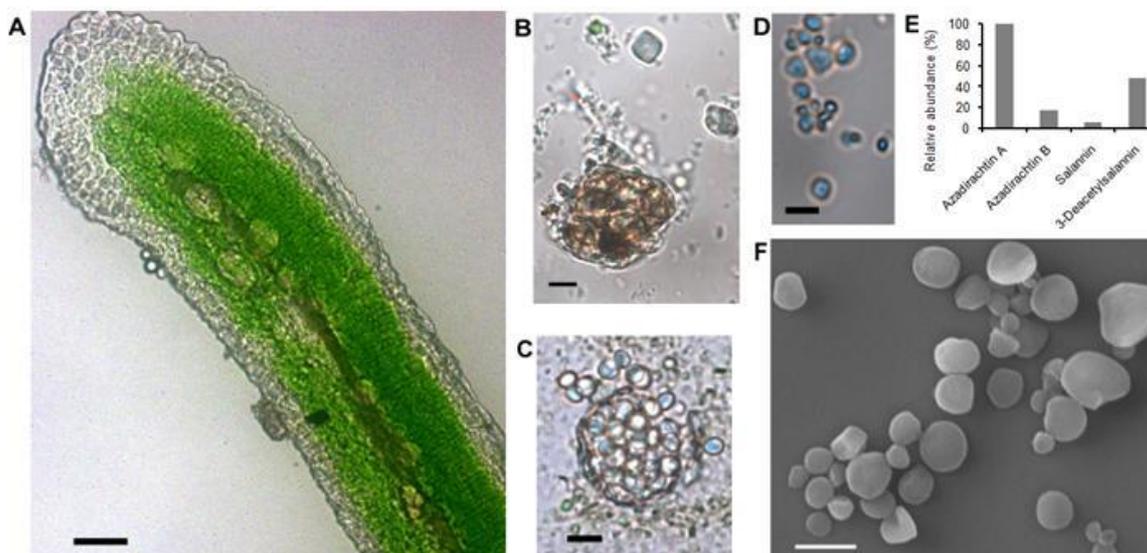

Figure 2B.7. Limonoid compartmentation in leaf tissue (A) transverse section of leaf, Bar = 50 μm . (B) leaf idioblast cell, Bar = 5 μm . (C) leaf idioblast protoplast, Bar = 10 μm . (D) micrograph of leaf idioblast vacuoles, Bar = 5 μm . (E) limonoid profile of leaf idioblast vacuoles. (F) electron micrograph of idioblast vacuoles obtained from leaves of *in vitro* grown neem seedling, Bar = 3 μm .

Neem idioblast cells of fruit pericarp and leaf showed red to brown coloration and interestingly, they seldom possess the fluorescent property as that of phenolics containing idioblasts of *Egeria densa*⁹⁹, indole alkaloid idioblast cells of *C. roseus*⁶¹ and *Camptotheca acuminata*¹⁰⁰. Neem idioblasts of pericarp and leaf possess numerous small vacuoles rather than a large central vacuole typical to other parenchymal cells and these vacuoles facilitate the accumulation of specific limonoids, characteristic of the individual tissues. Quantitative comparison of azadiradione and epoxyazadiradione in vacuoles and latex of pericarp suggested that vacuoles serve as a major site for limonoid accumulation over latex, in the fruit pericarp. Idioblast vacuoles isolated from the different tissues revealed limonoid profile corresponding the respective tissues (Figures 2B.4, 2B.5, 2B.7). Similar type of secondary metabolite idioblasts containing multitude of vacuoles has been observed in *Ruta graveolens* root and suspension culture, which are considered to be involved in storage of alkaloid, acridone¹⁰¹. Apart from the idioblast

vacuoles, central vacuole of barley was found to accumulate flavonoids whereas in the mesophyll vacuoles of *C. roseus*, presence of phenolics and indole alkaloids has been identified¹⁰²⁻¹⁰⁴.

2B.2.7. Morphology, anatomy and physiology of neem flower

Sectioning of floral petal was performed using vibratome to study the distribution of specialized cells involved in the storage of secondary metabolites. The sections of floral petals studied through light microscopy and scanning electron microscopy showed that, the petals possess non-glandular trichomes (Figure 2B.8A and 2B.8B). They were prevalent as either long or short hairs (Figure 2B.8A and 2B.8B). The long hairs reached up to 100 - 150 μm , whereas the length of short hairs was of 40 - 50 μm . Both the trichomes are unicellular and short hairs were abundant in numbers when compared to the long ones. The long non-glandular trichomes were found to be distributed across all floral parts.

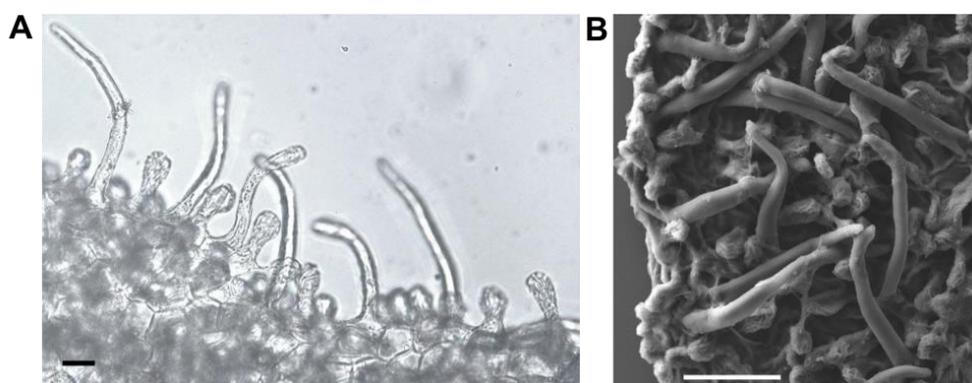

Figure 2B.8. Section of floral petal (A) Light micrograph showing two types of non-glandular trichomes on the surface, Bar = 20 μm , **(B)** eSEM image of trichomes on floral surface, Bar = 50 μm

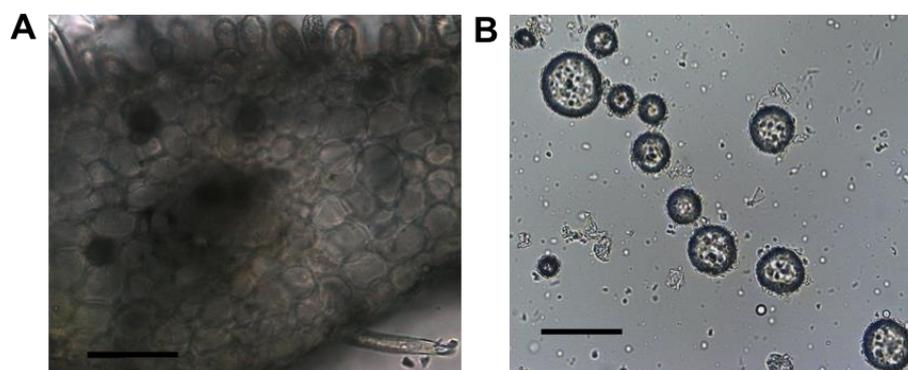

Figure 2B.9. Secretory vesicles of flower (A) Section of floral petal showing secretory vesicles, Bar = 50 μm . (B) secretory vesicles from flower, Bar = 50 μm

The cross section of the floral parts (Figure 2B.9A) showed brown colored secretory vesicles of varying sizes from 20 - 50 μm in diameter present in some of the cells. On density based centrifugal separation, these vesicles were obtained as a floating layer (Figure 2B.9B). These vesicles exhibited auto-fluorescence in red, green and blue channels and the merge of images obtained from 3 channels with the bright field shows bluish auto-fluorescence (Figure 2B.10B).

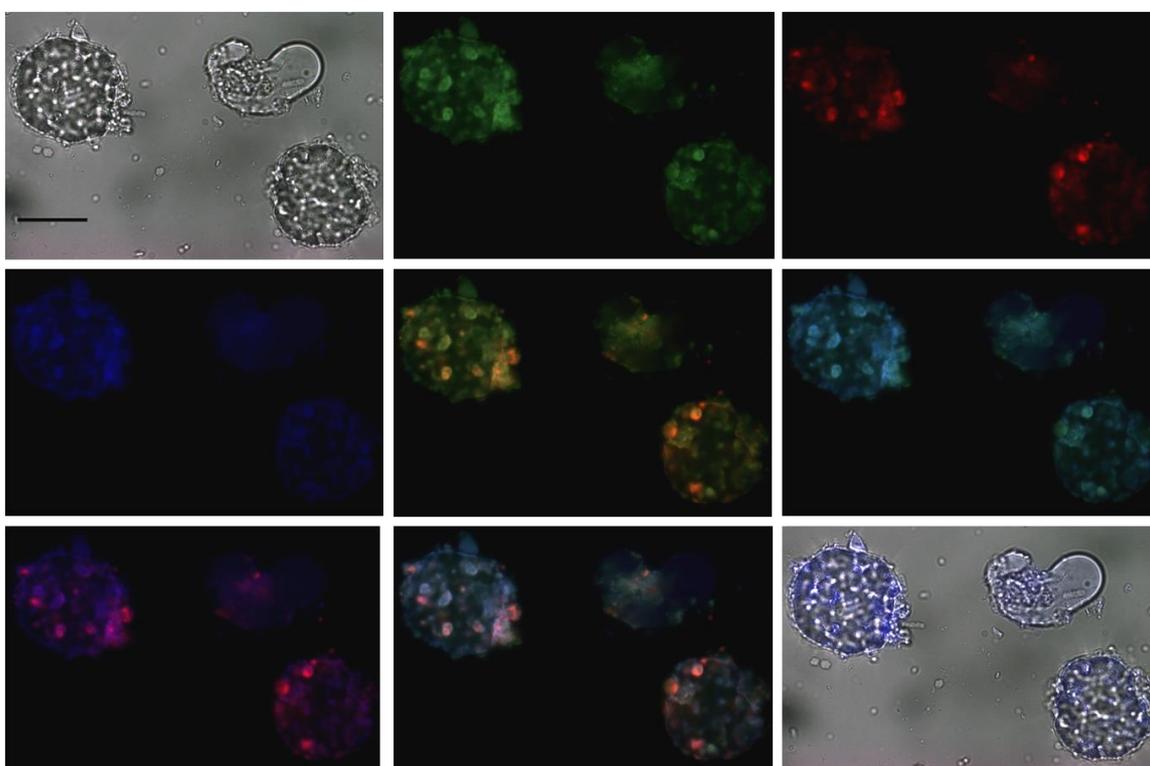

Figure 2B.10. Isolated secretory vesicles in epi-fluorescent microscopy, 1st, Bright-field image. 2nd, Green channel revealing autofluorescence. 3rd, Red channel revealing autofluorescence. 4th, Blue channel revealing autofluorescence. 5th, Merge of the green and red channel. 6th, Merge of the green and blue channel. 7th, Merge of red and green channel. 8th, Merge of all 3-channel images. 9th, Merge of all 3-channel images with corresponding bright-field image. Bar = 50 μm

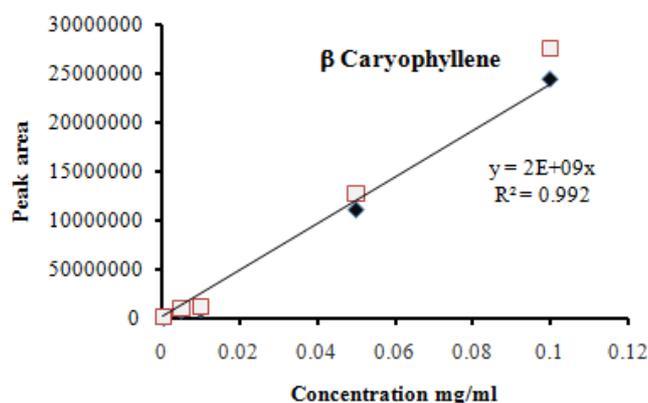

Figure 2B.11. Standard graph of β -caryophyllene constructed from the peak area of different standard concentrations in GC-QTOF analysis

Metabolic profiling of the isolated vesicles evidenced β -caryophyllene as the major sesquiterpene followed by γ elemene and humulene (Figure 2B.12). β -caryophyllene was quantified absolutely based on the standard curve made from different concentrations (Figure 2B.11). β -caryophyllene amounted to 0.01 mg/g of flower tissue and same quantity was found too in the isolated secretory vesicle (Figure 2B.12). Other sesquiterpenes identified in the flower are enumerated in Table 2B.2. LC-ESI-MS analysis showed that two monoacylglycerides such as palmitoyl and stearoyl glycerol were predominant in these vesicles (Appendix Figure 2B.5.3).

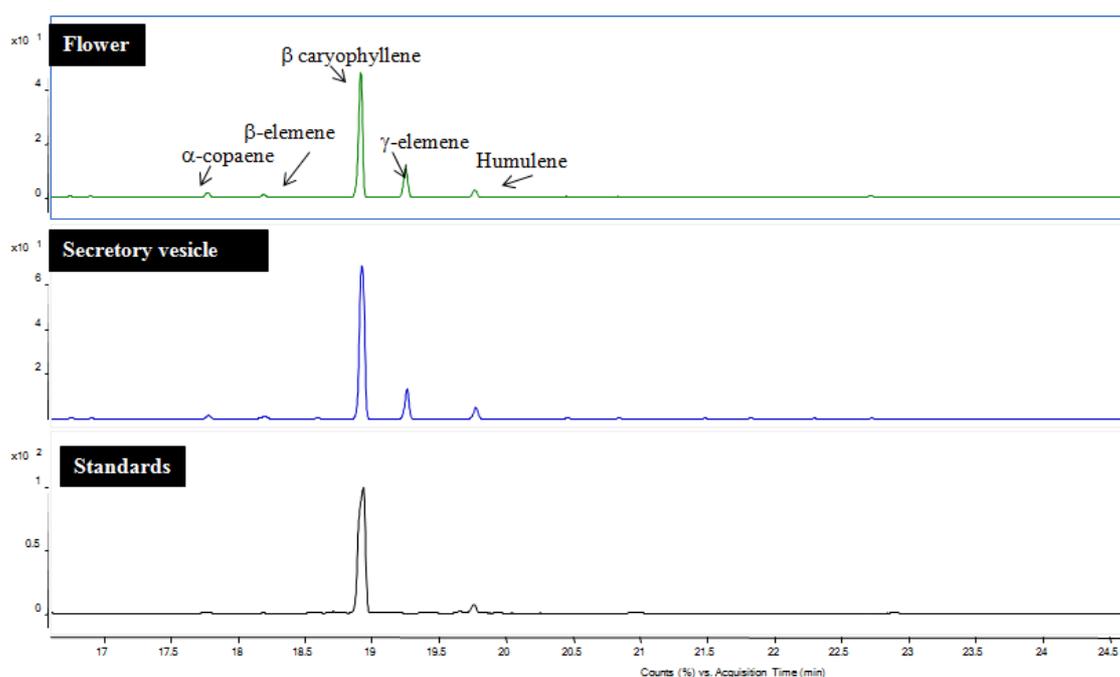

Figure 2B.12. Comparison of chromatogram of extracts from whole flower and isolated secretory vesicles with β caryophyllene and humulene standards.

Cross-section of floral parts also evidenced the presence of cytoplasmic accumulations of 0.5 – 2 μm size (Figure 2B.13A). These were isolated from the supernatant (Figure 2B.13B) and were found to contain long chain hydrocarbons (Figure 2B.13C).

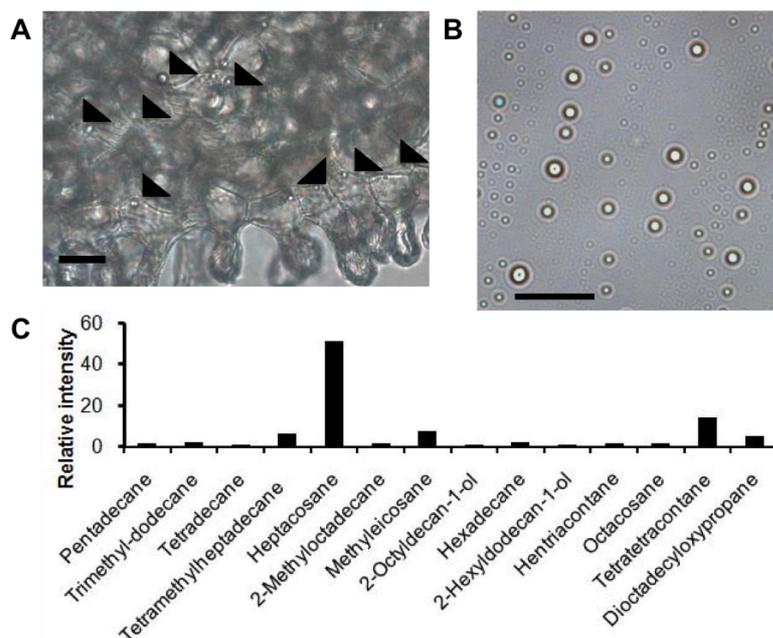

Figure 2B.13. Flower hydrocarbons (A) Section of floral petal showing cytoplasmic accumulations (marked with arrows), Bar = 20 μm (B) Isolated cytoplasmic accumulation bodies Bar = 10 μm (C) Relative intensity of hydrocarbons from flower.

Cross-section of anther showed pollen grains in the locule (Figure 2B.14A) and pollen exhibited green and blue autofluorescence evidenced through epi-fluorescence microscopy (Figure 2B.14B). Flavonoids emit in the blue region¹⁰⁵ and also, pollen grains are enriched in flavonoids (Figure 2B.15) and total flavanoids in flower was confirmed based on protonated, sodium adducts and based on MS/MS signature fragments (Figure 2B.5.4, Table 2B.3, Table 2B.4). Quantification of flavonoids in flower showed that glucosides were more abundant flavonoids followed by prenylated flavonoids and flavonol aglycones were relatively very low (Figure 2B.15). The autofluorescence exhibited by pollen grains of neem, was comparable to that of *Zea mays*¹⁰⁶ and can be found to be obtained due to the abundant occurrence of flavonoids in

pollen^{107, 108} and comparably, flavonoids were found to occur in tapetosomes in *Brassica*¹⁰⁹. Flavonoids are found to act as antioxidant and act as effective UV-B absorbers thereby helping the plants to cope up with environmental stresses¹¹⁰. It implies that flavonoids which act as protectant for plant, confers pharmacological and anti-oxidant properties for mankind.

Table 2B.4. Precursor fragments of flavonoids and its intensity obtained upon fragmentation at 30% NCE

Neem floral tissues contained only non-glandular trichomes, which in general are known to protect the surface of the plant parts from predators by acting as a physical barrier¹¹¹. Glandular trichomes are considered as a factory for biosynthesis of terpenes and these were not found in neem, instead the sesquiterpenes were identified to be localized in the secretory vesicles distributed across cells in all the parts of flower. These sesquiterpenes are presumed to be emitted through granulocrine secretion. Whereas, in *Marchantia thalli*, sesquiterpene lactones have been found to be localized in oil bodies⁷¹. The predominance of β -caryophyllene and elemene in flower suggests that they serves to attract pollinators¹¹² and also for the defense against pathogens as evidenced in *Arabidopsis*¹¹³. Moreover, sesquiterpene volatiles have been found to be biosynthesized in the anther and pollens in grapevine flowers¹¹⁴. From this study, it is known that storage of sesquiterpenes in secretory vesicles helps in secretion of them in appropriate conditions. Thus, these studies give the physiological importance of the metabolite localization in these tissues for specific functions in the tree.

2B.2.8. Comparison of idioblasts of fruit pericarp and leaves

Comparison of size, number and area occupied by idioblasts in different tissues of neem was compared with that of limonoid content of the respective tissues. Idioblasts in pericarp were concentrated adjacent to laticifers, which are abundant in the mesocarp, and were considered for enumeration of number of idioblasts. Number of idioblasts in the mesocarp of pericarp was 168/mm², whereas it was 130/mm² in the leaf (Figure 2B.16A). The area occupied by the idioblasts in each tissue was calculated (Figure 2B.16B) and found that idioblasts in mesocarp occupy maximum area of 0.32 mm²/mm² and in leaf; the area was found to be 0.04 mm²/mm². This data correlates with the limonoid content of these tissues as the pericarp was found to contribute for the maximum limonoid content followed by leaf⁴. The overview of different type of compartmentation existing in fruit and leaf tissues has been depicted in Figure 2B.16C, emphasizing the localization of different class of limonoids in those compartments of fruit.

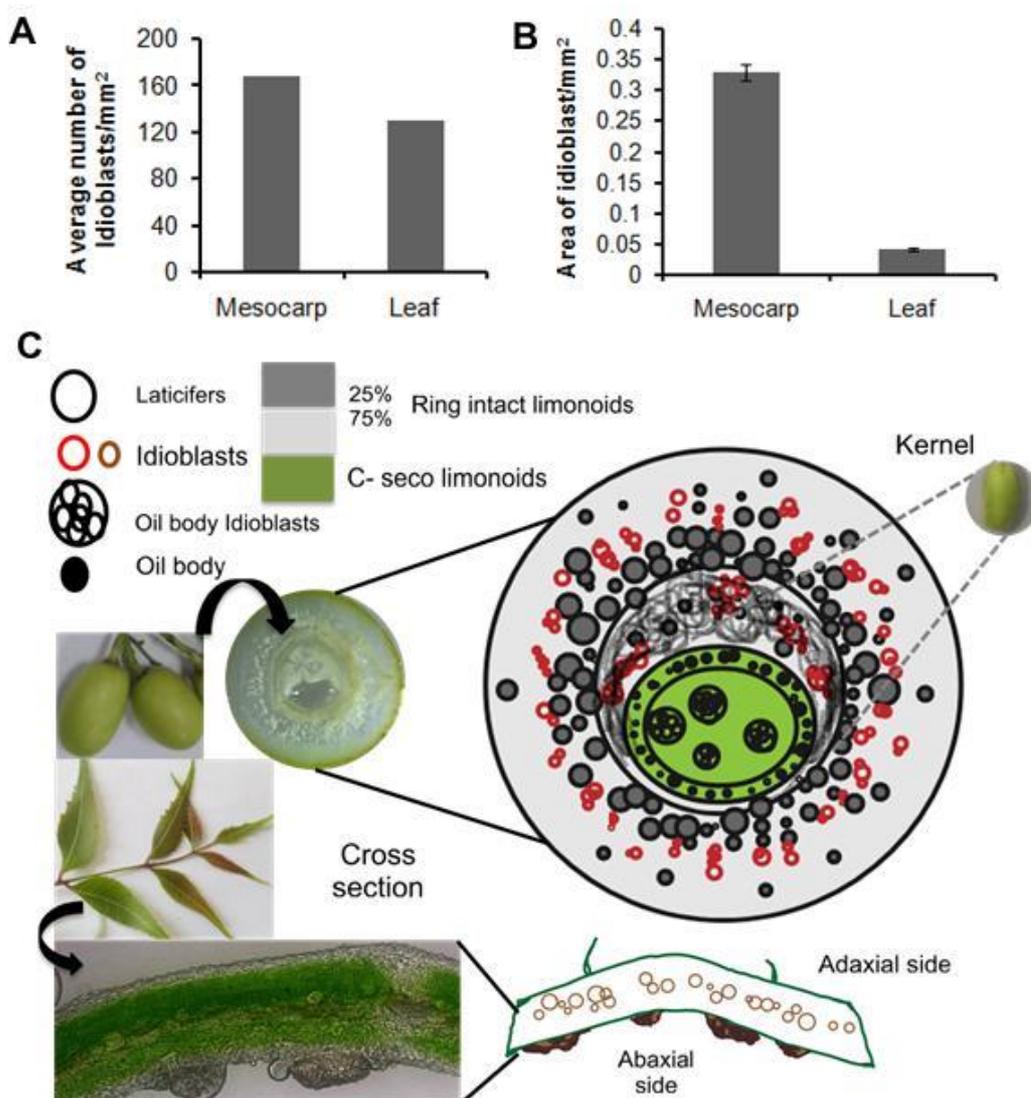

Figure 2B.16. (A) Number of idioblasts in different tissues and (B) their area contribution (C) Model showing cellular and subcellular compartmentalization of limonoids in neem fruit and leaf

2B.2.9. Feeding deterrence of neem fruit latex for insects

Laticifers are distributed across plant kingdom in order to impart defense response against insects and animals by exuding the cytoplasmic latex that are enriched with specialized metabolites⁸⁶. To understand further, the defensive action of the neem fruit latex, we performed no choice assay, dual choice assay and multiple choice assay with *Helicoverpa armigera*. In no choice assay, larvae of third instar were presented with a leaf disc treated with latex of 1 μ L, 5 μ L, 10 μ L, 20 μ L. The larvae didn't feed on the leaf disc treated with latex of 5 μ L and the volume above (Figure 2B.17). When it is force

fed with the latex treated leaf discs over the above mentioned amount of latex, it died. This shows that latex of 0.56 $\mu\text{L}/\text{cm}^2$ and above has feeding inhibition, physiological effects and mortality effects on insects.

In dual choice assay, *Helicoverpa armigera* was allowed into the plate containing the combination of latex treated and untreated leaf discs (Figure 2B.18). We found that, the larvae fed upon control leaf discs but did not consume the leaf discs which are treated with 0.56 $\mu\text{L}/\text{cm}^2$ and the above concentrations. However, larvae fed upon leaf discs treated at 0.112 $\mu\text{L}/\text{cm}^2$ but their body weight is reduced compared to that of the control larvae. Dual choice feeding assay was also performed with two latex treated and two control leaves containing plate in which two 3rd instar larvae were allowed (Figure 2B.19). The dual choice assay confirms the herbivory deterrence of the latex, which may be due to the contribution of the potentiation effect of all ring intact limonoids¹¹⁵ and traces of ring C-seco limonoids, in particular azadirachtin and its natural derivatives.

In multiple choice assay, 1 μg azadirachtin A (318 ng/cm^2), a potent insecticide was painted over the leaf disc along with 1, 5, 10, 20 μL latex treated and control leaf discs. The larvae preferred the control and 1 μL latex treated leaf discs to the above concentrations. When the larvae fed the azadirachtin treated leaf disc, it didn't feed further due to its anti-feedant effect.

Previous studies shows that EC_{50} of azadirachtin was 0.26 ppm, very effective and potent against *H. armigera*, when compared to other limonoids such as 6 β -hydroxygedunin, gedunin, salannin and nimbinene whose EC_{50} values are 24.2, 50.8, 74.5 and 391.4 ppm respectively⁸⁵. In our present study, it is well obvious that efficacy of different azadirachtin molecules, combined with the potentiation effect of different non-azadirachtin limonoids in latex gives evidence for the actual inhibitory effect of the neem fruit latex. The diverse limonoids present in the latex differ in their structure, hence their mode of actions such as feeding deterrence, physiological toxicity, growth inhibition, anti-feedant action etc. in combination are evidenced from the herbivory deterrence through choice assays with neem latex.

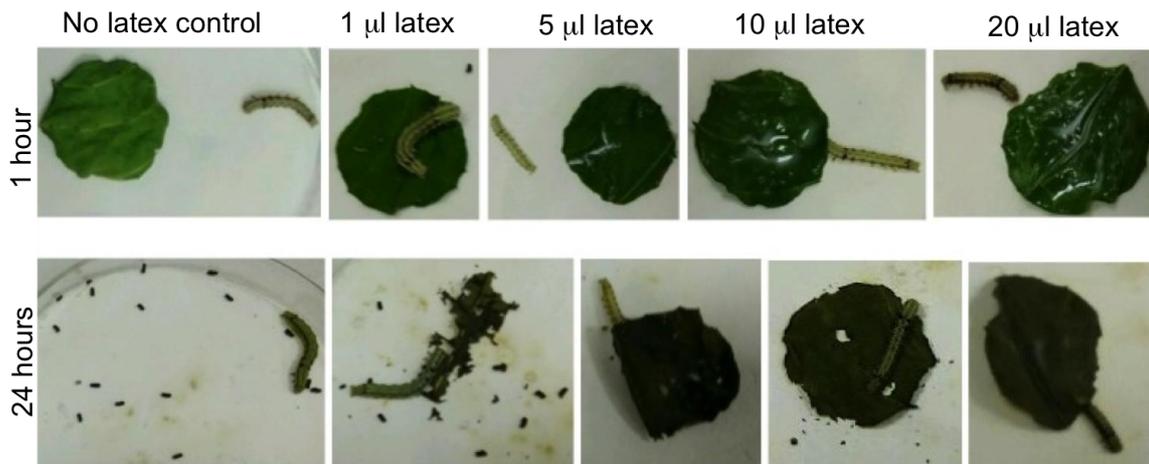

Figure 2B.17. No choice feeding assay with *Helicoverpa armigera*. 1st control leaf disc; In other plates leaf disc was treated with neem fruit latex of different volume.

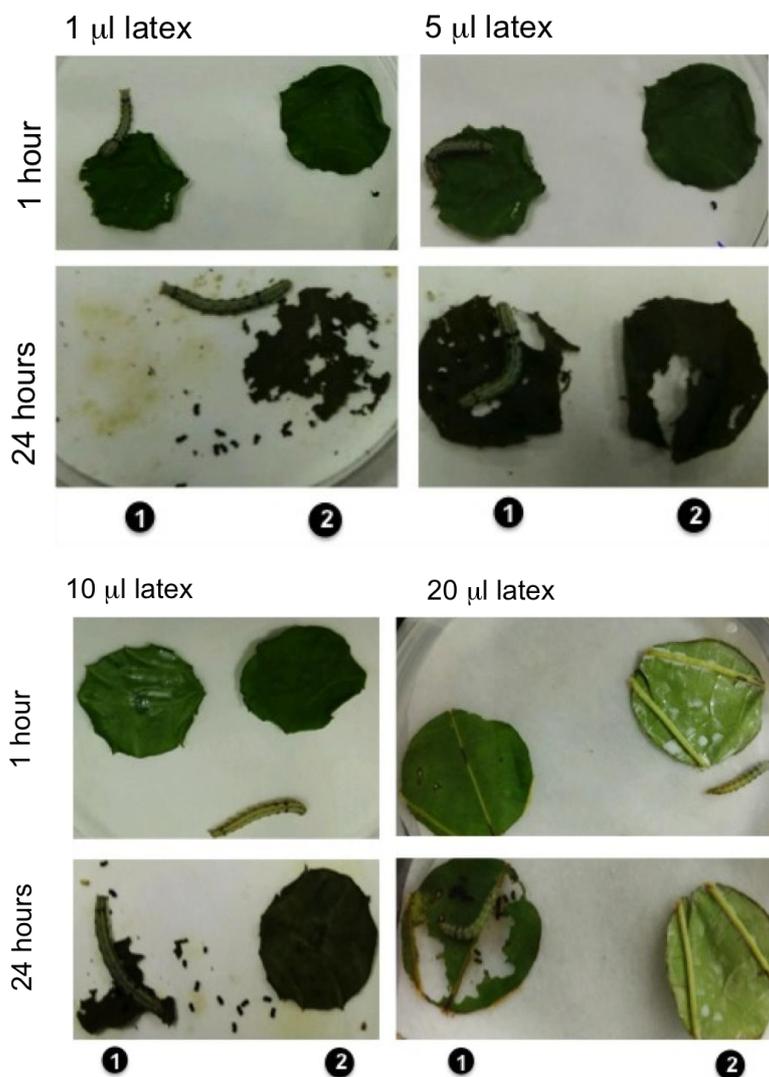

Figure 2B.18. Dual choice feeding assay with *Helicoverpa armigera*. 1, control leaf disc; 2, leaf disc treated with neem fruit latex of different volume (A) For 12 hours; (B) 24 hours.

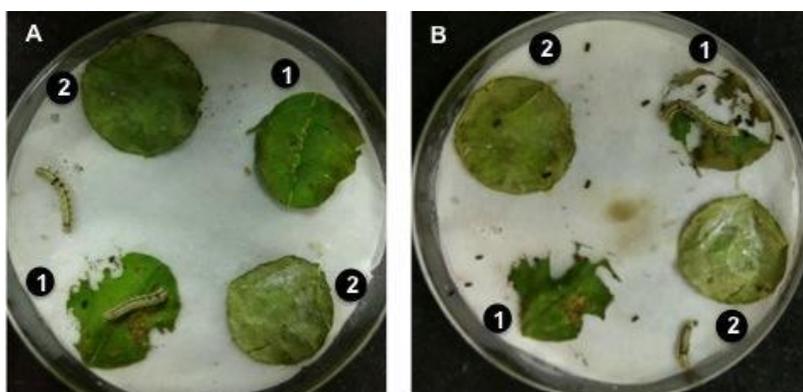

Figure 2B.19. Dual choice feeding assay with 2 *Helicoverpa armigera* /plate. 1, control leaf disc; 2, leaf disc treated with neem fruit latex of 2.24 $\mu\text{L}/\text{cm}^2$ (A) For 12 hours; (B) 24 hours.

Figure 2B.20. Multiple Choice feed assay 1, control; 2, 1 μL latex; 3, 5 μL latex; 4, 10 μL latex; 5, 20 μL latex; 6, 1 μg azadirachtin A

2B.3. Conclusion

Though, the localization of each step of limonoid biosynthetic pathway remains unclear, and can be understood only after the characterization of enzymes involved in different steps of the pathway, localization of different limonoids and other metabolites in specific intracellular compartments such as oil bodies, idioblast vacuoles, secretory vesicles and latex, the cytosol of laticifers is presented through our studies. Our present investigation will help to study the future prospect of identification of limonoid biosynthetic pathway steps in the individual organelles and latex, their biosynthesis, translocation, the underlying regulatory interplay involved etc. It also provides valuable insights into the exemplary compartmentation existing for efficient triterpenoid

accumulation in *A. indica*, notably mediated by specialized cell types and organelles. Interrogation into the above perspectives will give an understanding to efficiently engineer a heterologous system through synthetic biology approach for the production of C-seco limonoids and intermediates.

2B.4. Materials and methods

2B.4.1. Plant materials

Neem leaves, flowers, and fruits were collected from a tree in CSIR-NCL campus during the month of March-August. Latex was collected from the fresh fruits in its second to third stage of development for various experiments. For the initiation of cell culture, fruits in third to fourth developmental stages were collected.

2B.4.2. Extraction of limonoids from neem fruit latex

Fresh, unripe neem fruits were lanced with a surgical blade at the bottom in the pericarp region to collect the milky latex. The latex was dissolved in water and extracted thrice with equal volume of n-hexane. The hexane extract was concentrated under reduced pressure to dryness. The extracted latex was again re-extracted with equal volume of ethylacetate thrice and the pooled ethylacetate extract was concentrated under reduced pressure, reconstituted in LCMS grade methanol and analyzed using thin layer chromatography (TLC). TLC was performed on pre-coated Merck silica gel plates (TLC Silica gel 60 F254) using the solvent system ethylacetate: hexane (10:90) and the spots were visualized under UV lamp and developed using charring reagent (92% ethanol, 3.2% anisaldehyde, 2.8% H₂SO₄ and 2% AcOH). To further identify the limonoids in traces, the diluted extract was injected in LC-ESI-MS as described below.

2B.4.3. Tissue sectioning and microscopy

Neem kernel, pericarp, leaf and flower were embedded in 4% agarose and subjected to slicing, using vibrating blade microtome (Leica) of speed and amplitude set at 30 mm/s and 20 mm respectively until a section of 20-30 micron thickness was obtained. Cross section of pericarp was visualized under stereomicroscope (Leica) to study the distribution of laticifers. The kernel sections were stained with Toluidine Blue for the identification of idioblast cells and Nile Red for discriminating the lipophilic

nature of the organelle. It was then visualized with Axio Observer.Z1 (Carl Zeiss) under bright field and epi-fluorescence microscopy under red, green and blue filters. Neem fruit latex was diluted 250 fold and visualized under $\times 63$ objective and it was further stained with Toluidine Blue, Oil Red O, Lugol's iodine and Nile Red (Sigma Aldrich). Nile Red stained latex were imaged in AxioobserverTM LSM 710 Carl Zeiss laser scanning confocal microscope with a $\times 63$ Plan-Apochromat 1.4 NA oil immersion objectives respectively. The sample was excited with the 514-nm line from the argon laser, and the emitted light was collected at two different ranges from 648 to 698 nm and 525 to 567 nm⁹³.

2B.4.4. Environmental Mode Scanning Electron Microscopy and Transmission Electron Microscopy of latex

For scanning electron microscopy, neem latex was collected in 0.1 M phosphate buffer, pH 7.4 with 0.4 M mannitol and 6% glutaraldehyde. Diluted, fixed and dried sample was then subjected to eSEM, FEI Quanta 200 3D. The scale bar for all the eSEM images was made using ImageJ software. Fixed and diluted latex was placed on copper grids (400 mesh, Carbon type B) for transmission electron microscopy. For contrasting the grids, uranyl acetate was used. Electron micrographs were obtained at 120 kV with Tecnai-T20.

2B.4.5. Isolation of neem protoplasts from different tissues and limonoid profiling

Neem protoplasts were prepared from different tissue like fruit pericarp, kernel and leaves by modifying the method as described previously¹¹⁶. In brief, the neem tissues were cut into small pieces of 2 mm size in the presence of cell protoplast washing media (CPW) of following composition, 0.75 M mannitol, 10 mM CaCl₂, 10 mM MES at pH 5.8, 0.1% BSA and incubated in dark for 2 hrs for plasmolysis. In case of pericarp tissue, the latex was exuded from the fruit and the pericarp tissue was washed with CPW buffer to remove remnants of latex, henceforth the pericarp laticifers were devoid of latex. The plasmolysed tissues were transferred to CPW containing enzyme mixture of cellulase 1.5%, pectinase 2%, and hemicellulase 1% (Sigma Aldrich) and incubated in dark for 16 hours with intermittent shaking every hour. After enzyme digestion, the mixture was vigorously shaken for few seconds and filtered through muslin cloth to

remove pieces of tissue and the protoplast pelleted at 100 g and washed thrice with CPW containing 0.55 M mannitol. The protoplast pellet was resuspended in the following buffer, MES pH 5.8, 10 mM CaCl₂, and 0.1% BSA and 0.6 M sucrose. The resuspended protoplasts were visualized through optical microscope. Extraction of limonoids from different tissue protoplasts was carried out using dichloromethane thrice and the extract was concentrated under reduced pressure, later reconstituted with LC-MS grade methanol for ESI-LC-MS. In case of *in vitro* leaves, the tissue was subjected to enzyme treatment for 5 hours.

2B.4.6. Isolation of oil bodies from kernel and vacuoles from fruit, leaves and limonoid profiling

Oil bodies were isolated from neem kernel from the modification in protocol as reported earlier⁹³. Neem kernels were homogenized in the presence of CPW solution (5 mL/100mg) and subjected to sonication for 2 min. The homogenized cells were centrifuged at 1000 × g for 10 min. The floating layer obtained was visualized in microscope. For histochemical analysis, the kernel was fixed in the same solution mentioned above in the presence of 6% glutaraldehyde and subjected to homogenization and centrifugation as described above. The oil body layer obtained was stained with Nile Red stain and imaged using confocal microscope at ×100 oil immersion objective of confocal microscope as described earlier. To remove the oil bodies from the cells completely, the above-described process was repeated several times, by centrifugation at 10000 × g. Complete extraction of oil bodies from kernel resulted in the observation of vacuoles in the kernel tissue. The oil bodies and kernel residues were subjected to extraction for limonoids as described above. The pericarp tissue was pulverized in the presence of CPW solution and the solution obtained was fixed in the presence of glutaraldehyde as described above and the fixed solution was filtered through filter paper of 10 μm pore size to remove the debris. The filtrate was visualized for the vacuoles with light and electron microscopy. For the isolation of vacuoles from leaves, the leaves from *in vitro* grown plants was subjected to protoplast isolation as described above, whereas the incubation time with enzyme mixture was increased to nine hours. The idioblast vacuoles were released from the protoplasts and the vacuoles formed as a

white layer in the protoplast pellet. The white layer was subjected to filtration and fixation as stated above, to study the morphology of vacuoles through eSEM.

2B.4.7. Isolation of vesicles, pollen and cytoplasmic droplets from flower

The flower tissue was subjected to homogenization into fine powder under liquid N₂. The homogenized powder was constituted in CPW buffer (5mL/g) and mixed evenly⁹³. The homogenate was centrifuged at 3500 ×g and the floating layer was collected in a separate tube, which contained secretory vesicles and pollen grains. The pollen grains settled down at the bottom of the tube in few hours. The floating layer and settled pollen grains were subjected to filtration through filter paper of pore size 10 micron and the filtrate contained the cytoplasmic droplets. The three fractions were extracted with n-hexane followed by ethylacetate thrice and the pooled extracts were concentrated to dryness under reduced pressure. The pooled extract of vesicular fraction was passed through glass wool to remove the remnants of fused vesicle residues. The extracts were re-dissolved in methanol and n-hexane for analysis in LC-ESI-MS and GC-QTOF respectively as per the conditions described below.

2B.4.8. LC-ESI-Mass Spectrometry conditions

Analysis of neem limonoids was performed through target and untargeted profiling, with Thermo Scientific QExactivTM hybrid quadrupole-Orbitrap mass spectrometer associated with Accela 1250 pump and Accela open AS. The conditions of HESI source include capillary temperature of 320 °C, Heater temperature at 350 °C, s-lens RF level of 50, spray voltage of 3.6 kV, spray current of 0.9 μA with sheath gas flow rate of 41, Auxiliary gas flow rate of 9 and sweep gas flow rate of 3. Standards as well as the extracted samples were analyzed in positive ionization mode, in full MS-scan with scan range of 80 to 1000 *m/z*. Following were the properties of the scan performed-resolution 70,000, AGC target 1e6, Maximum IT 200 ms. Waters Acquity UPLC BEH C₁₈ column (particle size 1.7 μm, 2.1 X 100 mm) was used as the stationary phase while the solvent system of methanol and water containing 0.1% formic acid served as the mobile phase. The gradient started with 40% methanol (5 min isocratic), it was then increased to 50% (5 min isocratic), followed by 60% methanol for the next 15 minutes and over the next 4 minutes it was isocratic with 65% methanol. It was then increased to

90% methanol for 4 minutes. For the last 2 minutes, it was isocratic with 40% methanol. Constant flow rate of 0.3 mL min⁻¹ was maintained throughout the run time of 35 min. The chromatogram and mass spectral data were processed by Xcalibur qual browser (version 2.3; Thermo Scientific). 15 limonoids were confirmed based on the authentic standards isolated, purified and characterized from neem⁴. Further, MS/MS for all the identified limonoids through was performed in PRM mode, with protonated adduct as precursors in inclusion list. 20% NCE was employed for C-seco limonoids and 25% for ring intact limonoids at MS resolution of 35000, whereas for confirmation of flavonoids 30% NCE was used at a resolution of 17500. Quantification of flavonoids was carried out relative to the known concentration of authentic standard Kaempferol (Sigma Aldrich).

2B.4.9. GC-MS analysis

The extract was reconstituted in n-Hexane and it was analyzed by a 7890B Gas Chromatograph coupled to an Accurate-Mass Q-TOF GC/MS 7200 (Agilent Technologies). Separation was performed by using 30 m × 250 μm × 0.25 μm HP-5 capillary column with helium as a carrier gas at a flow rate of 1 mLmin⁻¹. The extract of 1 μL was injected in splitless mode. The temperature program was set at 60 °C for 2 min, followed by a temperature gradient from 60 °C to 250 °C at a ramping rate of 5 °C/min, and held at 250 °C for 14min. Sesquiterpenes and hydrocarbons were identified by matching the acquired mass spectra with the reference library (National Institute of Standards and Technology) using Agilent MassHunter Qualitative analysis tool (B.06.00). Standard curve for β caryophyllene (Sigma-Aldrich) was made for quantification of it in the whole flower and also in the isolated secretory vesicles. Standard curve was made with β caryophyllene of different concentrations such as 0.1 mg/ml, 0.05 mg/mL, 0.01 mg/mL, 0.005 mg/mL, 0.001 mg/mL.

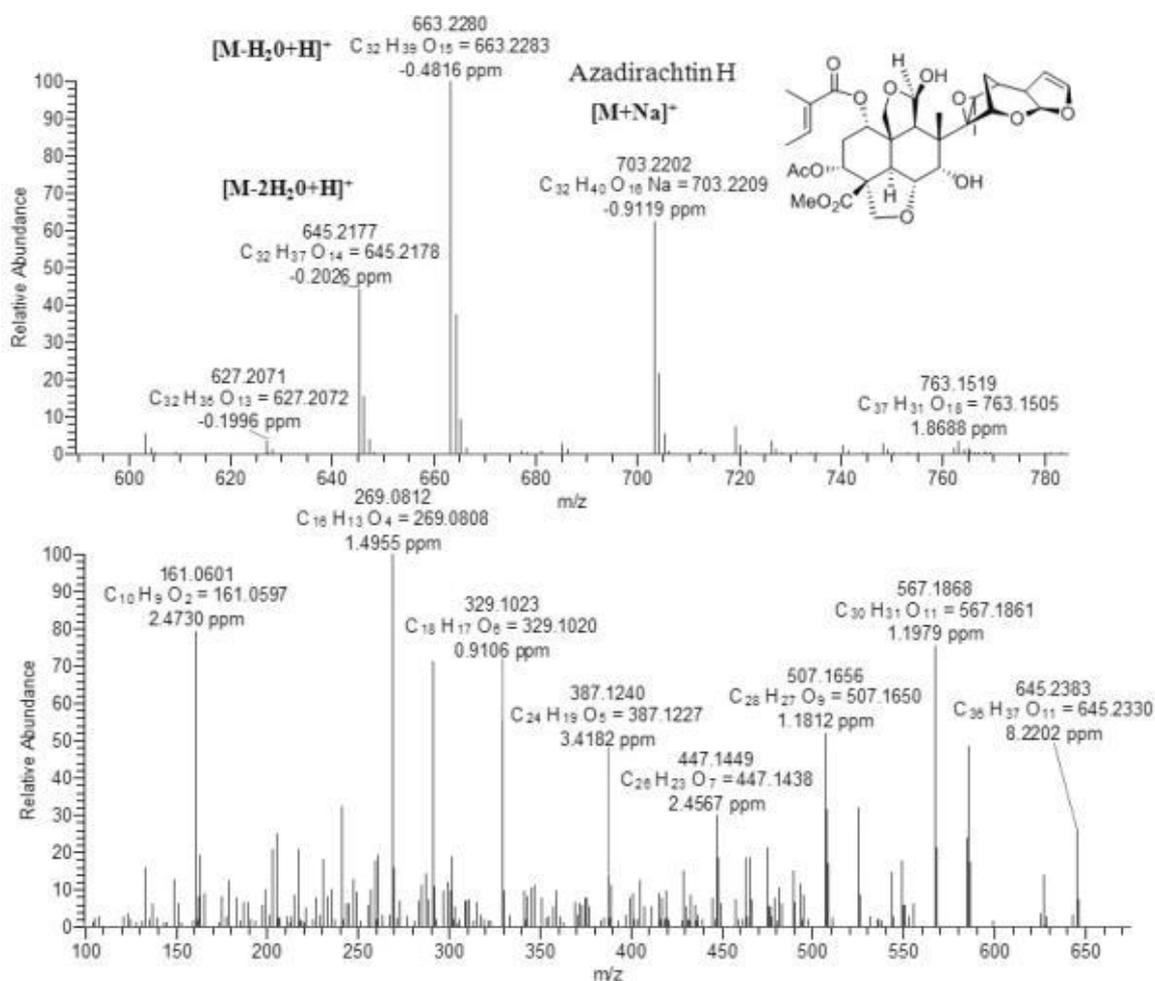

2B.4.10. Feeding assay with neem fruit latex

Feeding-choice assay was performed with third instar larvae of *Helicoverpa armigera*. The larvae were reared on an artificial diet in the laboratory and they were starved for 4 h before each assay. Freshly collected leaves of *Ricinus communis* were cut into 2.8 cm diameter discs using cork borer and were used as feed for the larvae. Neem

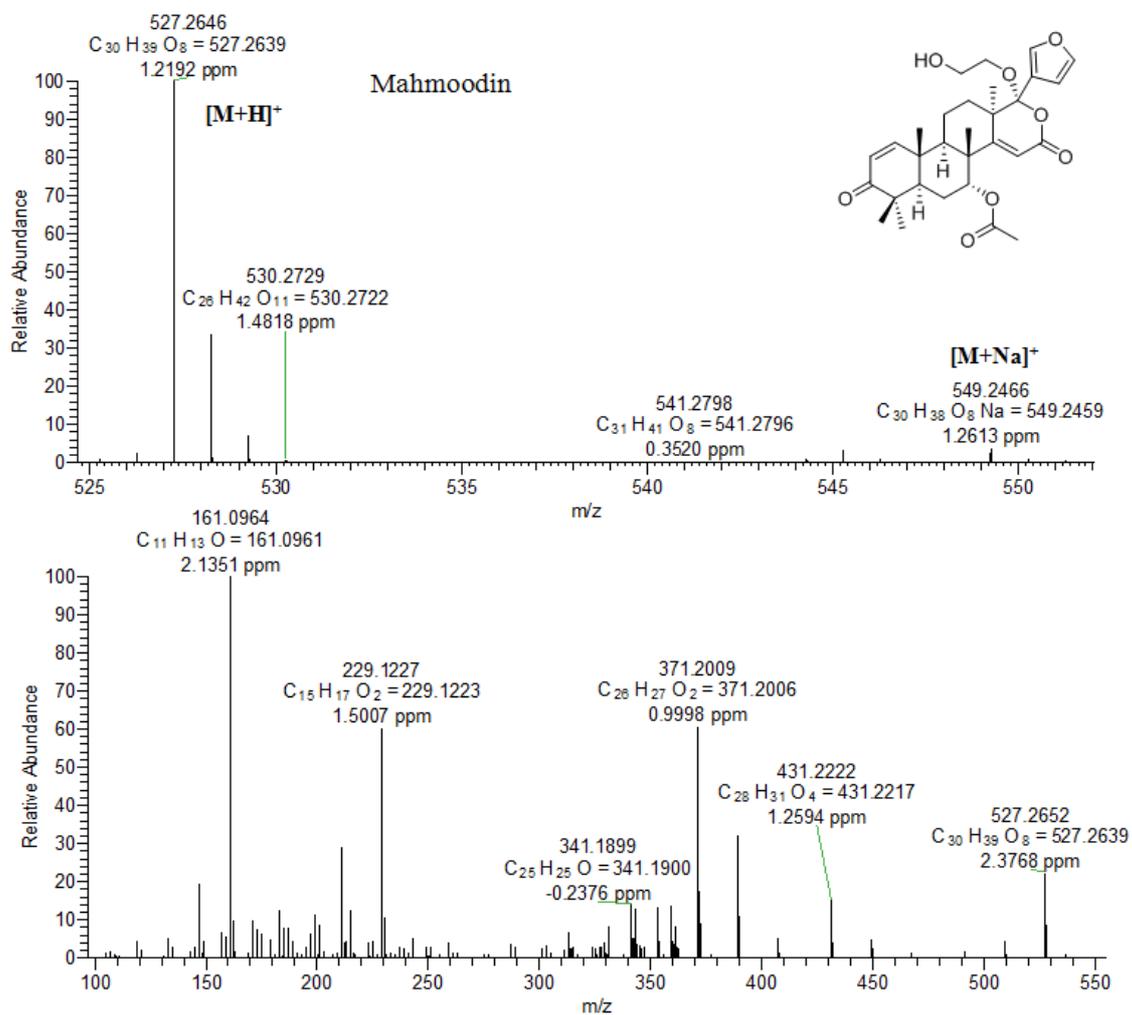

fruit latex (0.112, 0.56, 1.12 and 2.24 $\mu\text{L} / \text{cm}^2$ painted on both adaxial and abaxial side of leaf disc). In no choice assay, over a petridish containing moistened filter paper, a treated leaf disc was placed. In dual choice feeding assay, both latex treated and untreated (control) leaf discs were placed in a plate. In another dual choice assay, the treated and untreated leaf discs were placed at alternating positions, with 2 larvae each left at the center. In multiple choice assays, total of 6 leaf discs were placed each of 2 cm in diameter, the control and azadirachtin treated leaves discs were presented along with four latex treated leaf discs. The experiment was performed in duplicates and the feeding preference of the larvae for the treated and untreated leaf discs were monitored for 24 hours.

2B.5. Appendix

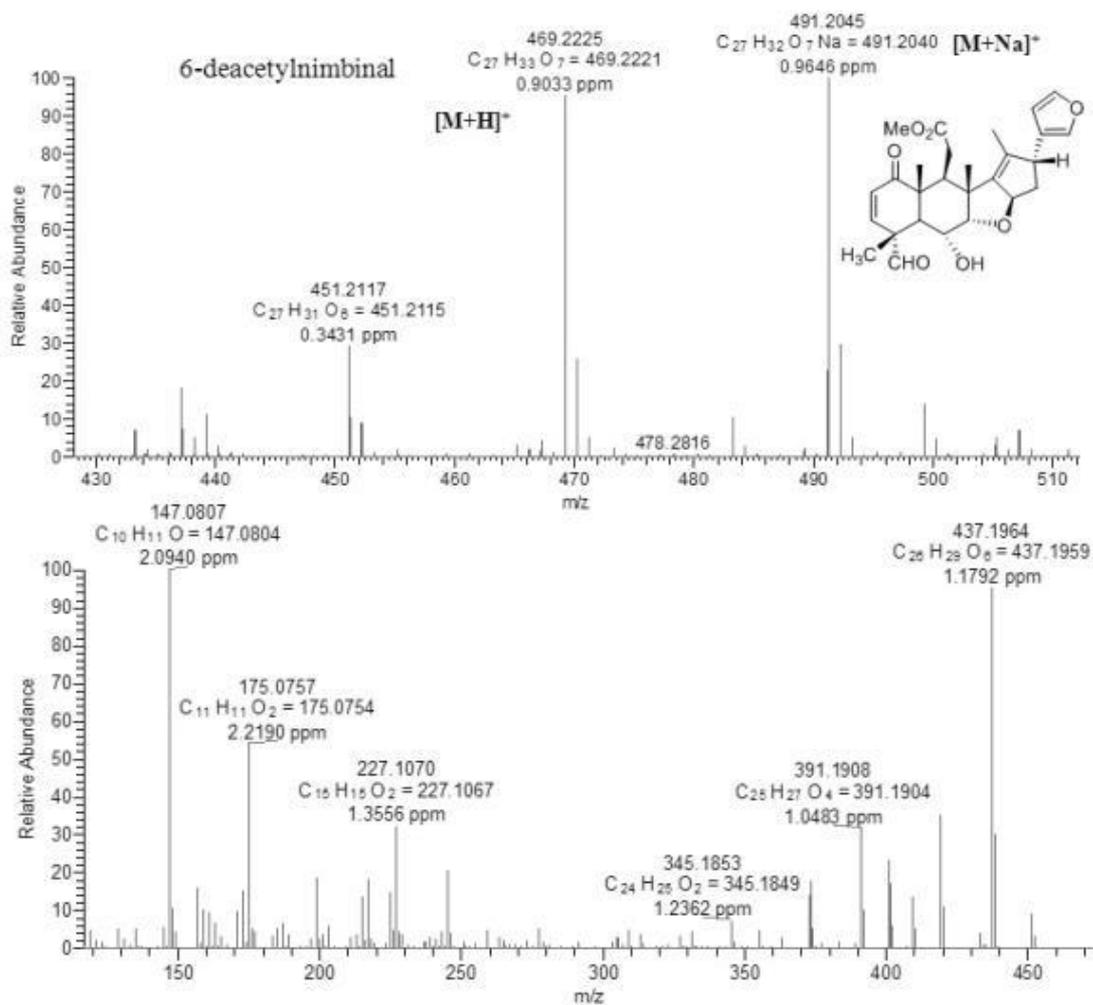

Azadirachtin H

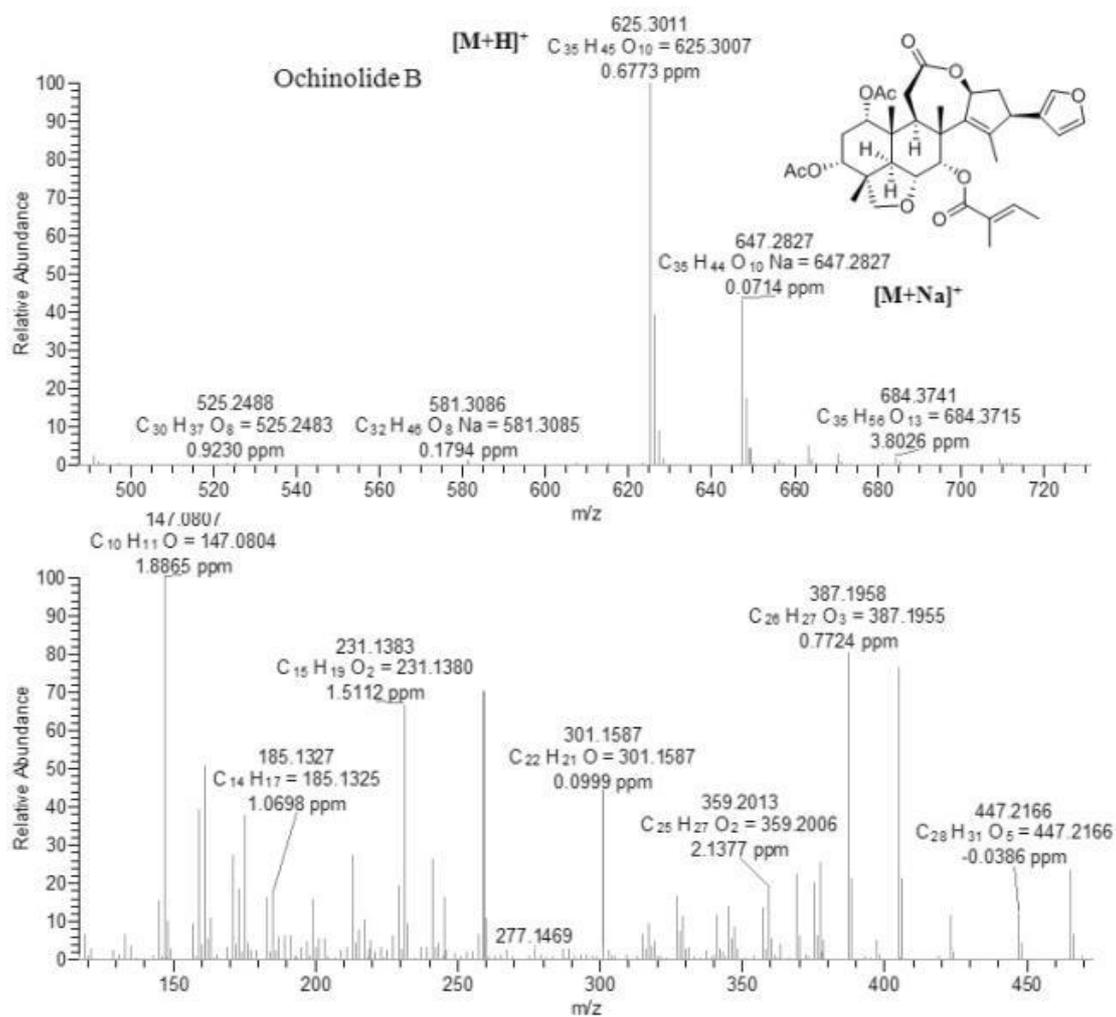

Mahmoodin

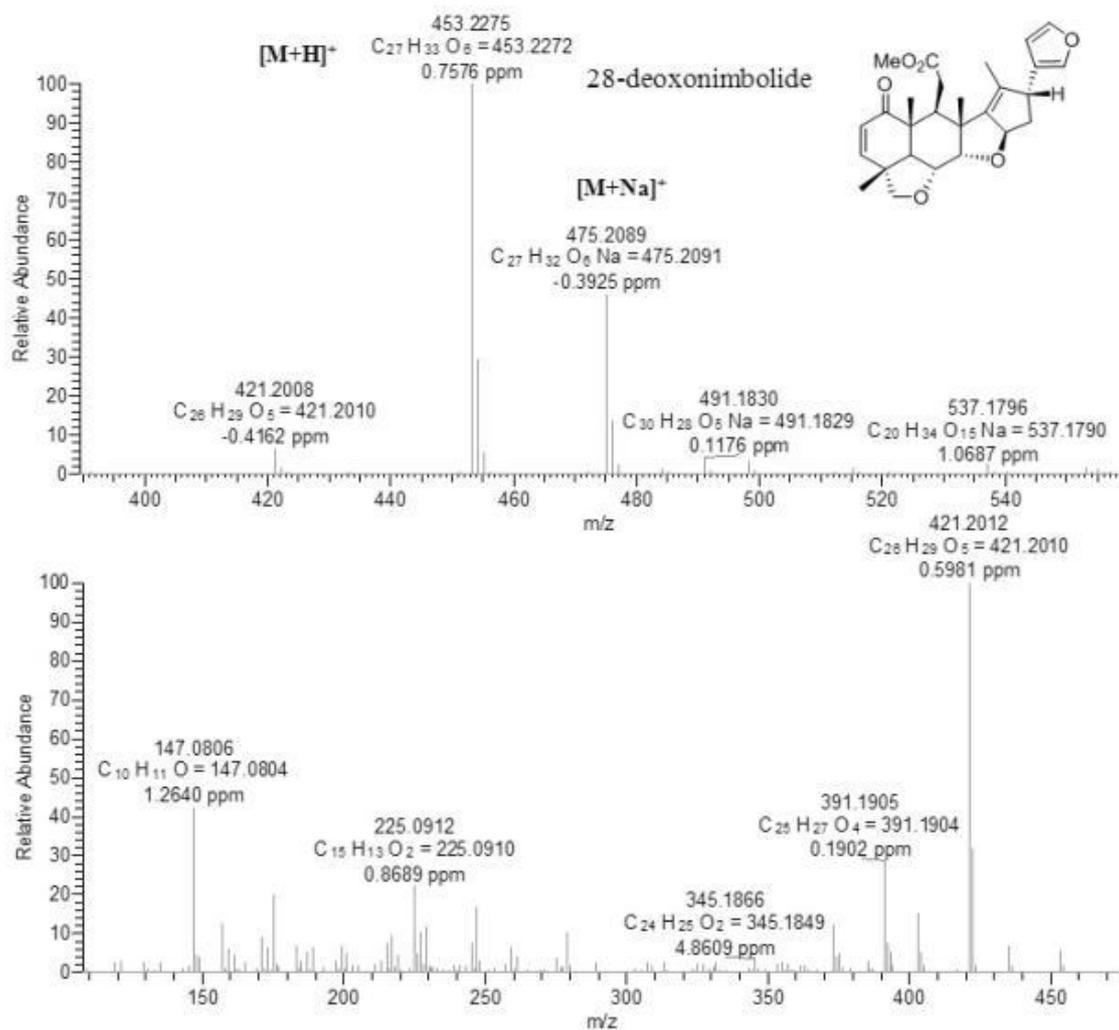

6-deacetylnimbinal

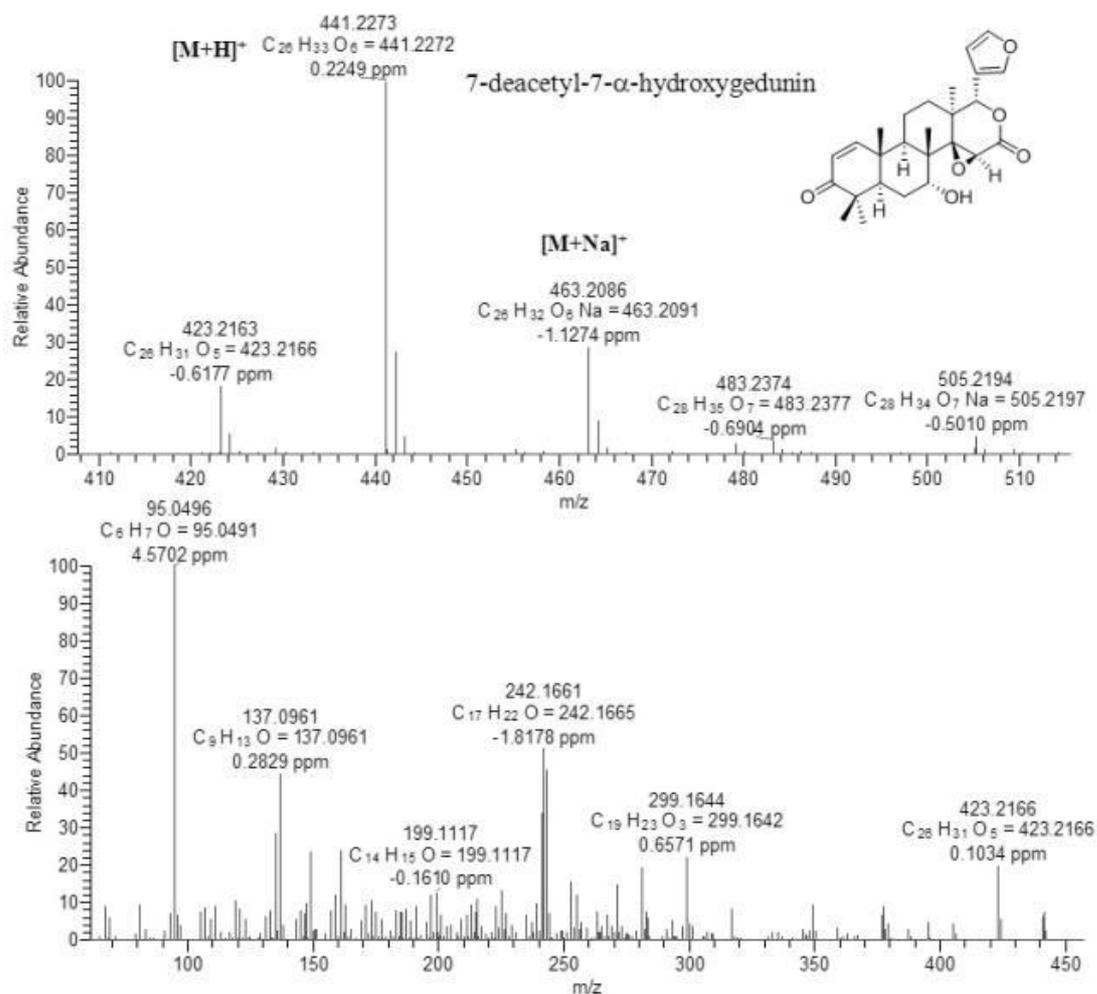

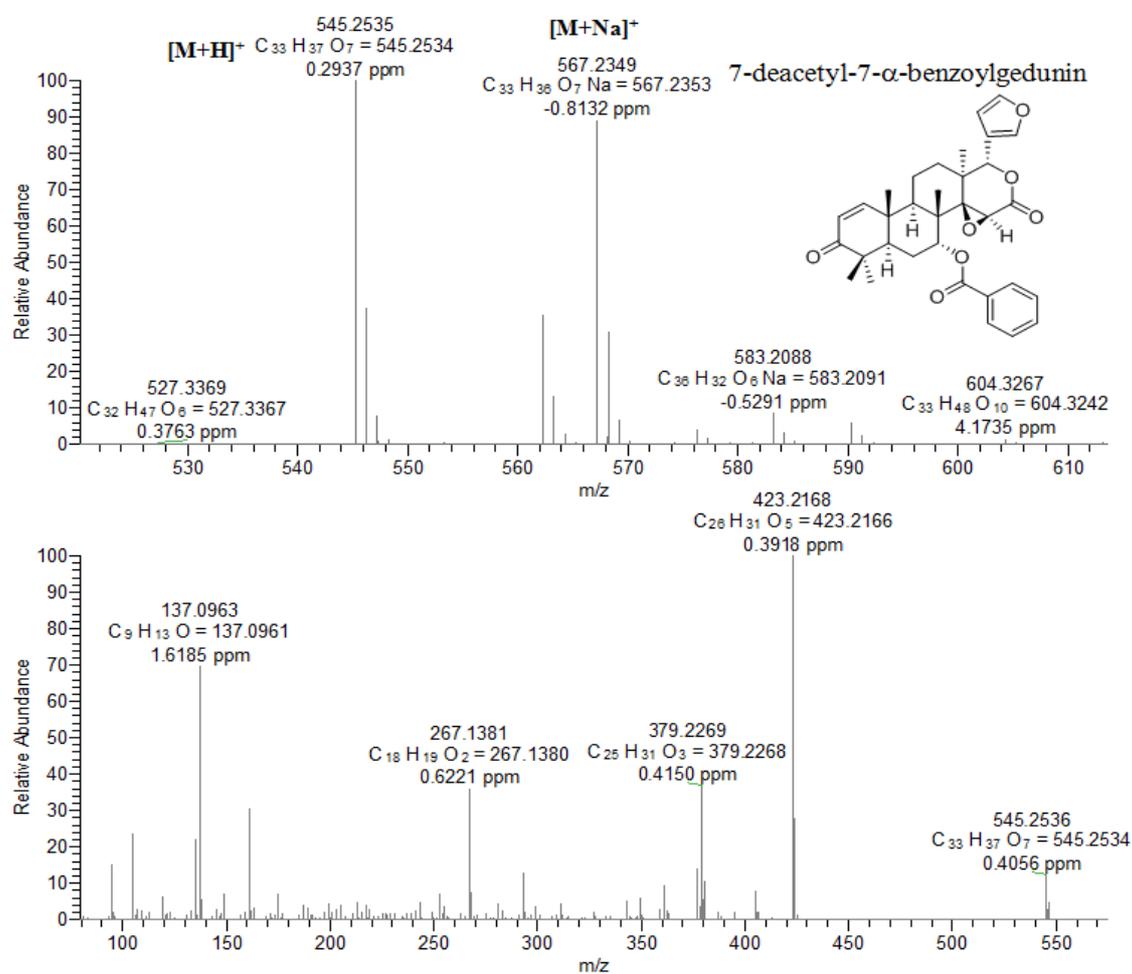

Ochinolide B

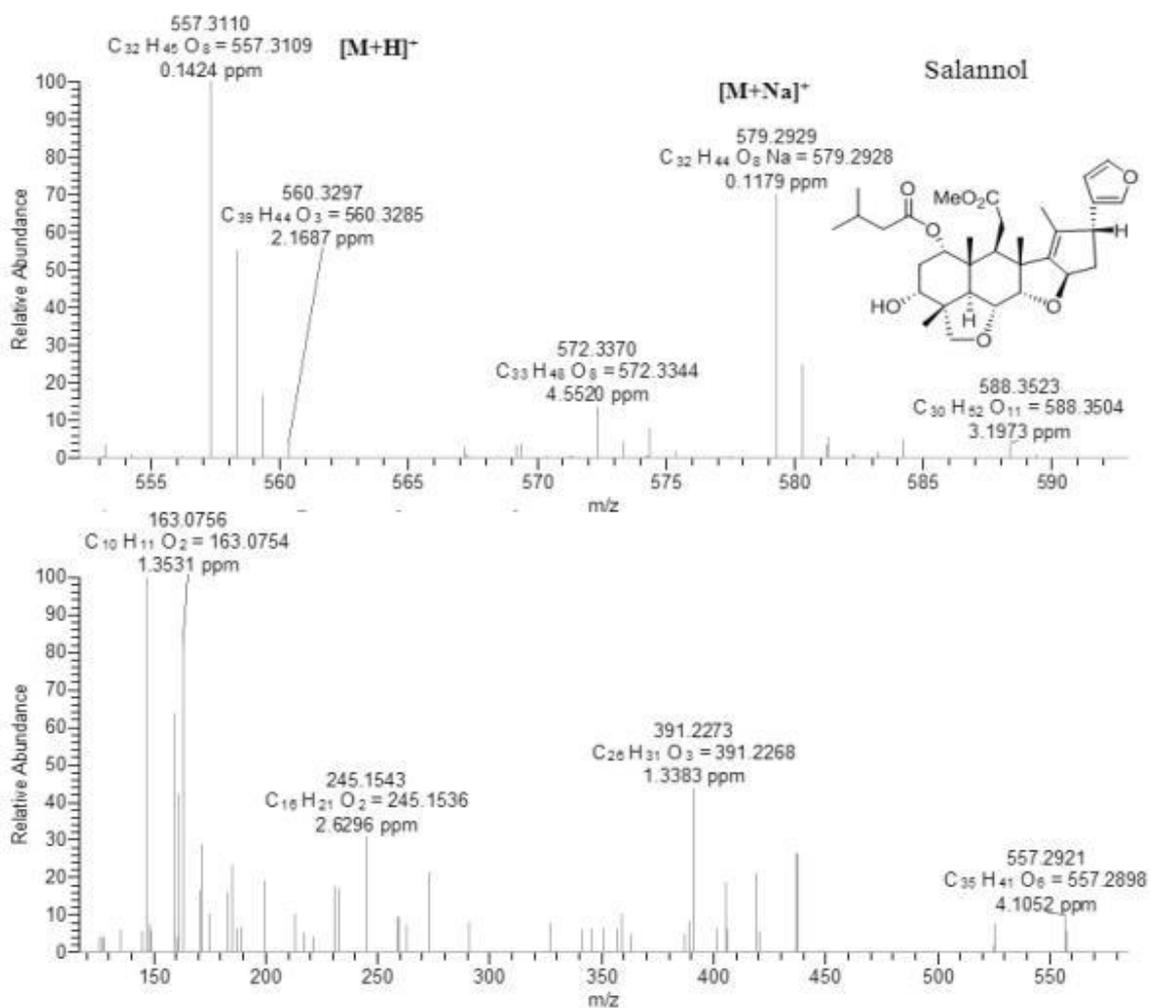

28-deoxonimbolide

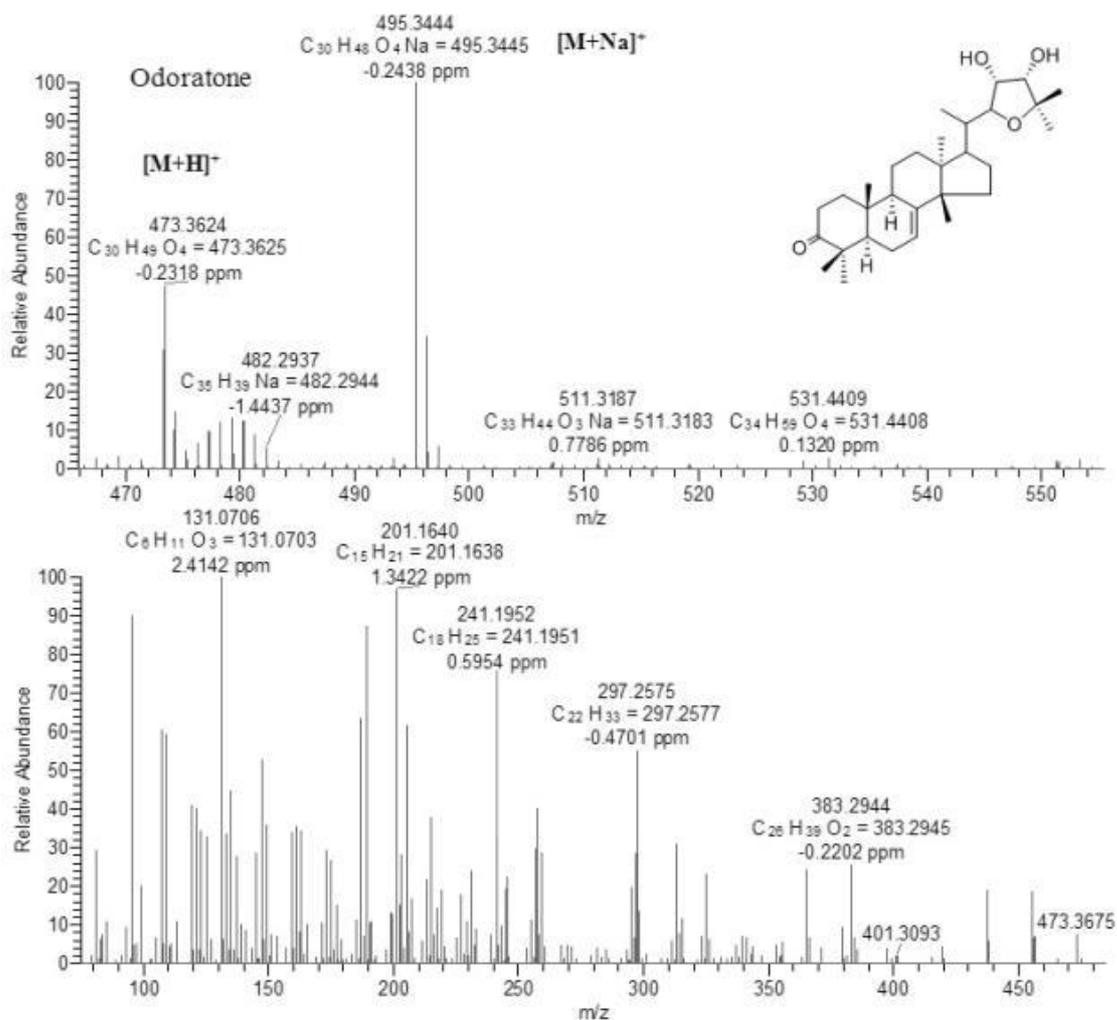

7-deacetyl-7- α -hydroxygedunin

7-deacetyl-7- α -benzoylgedunin

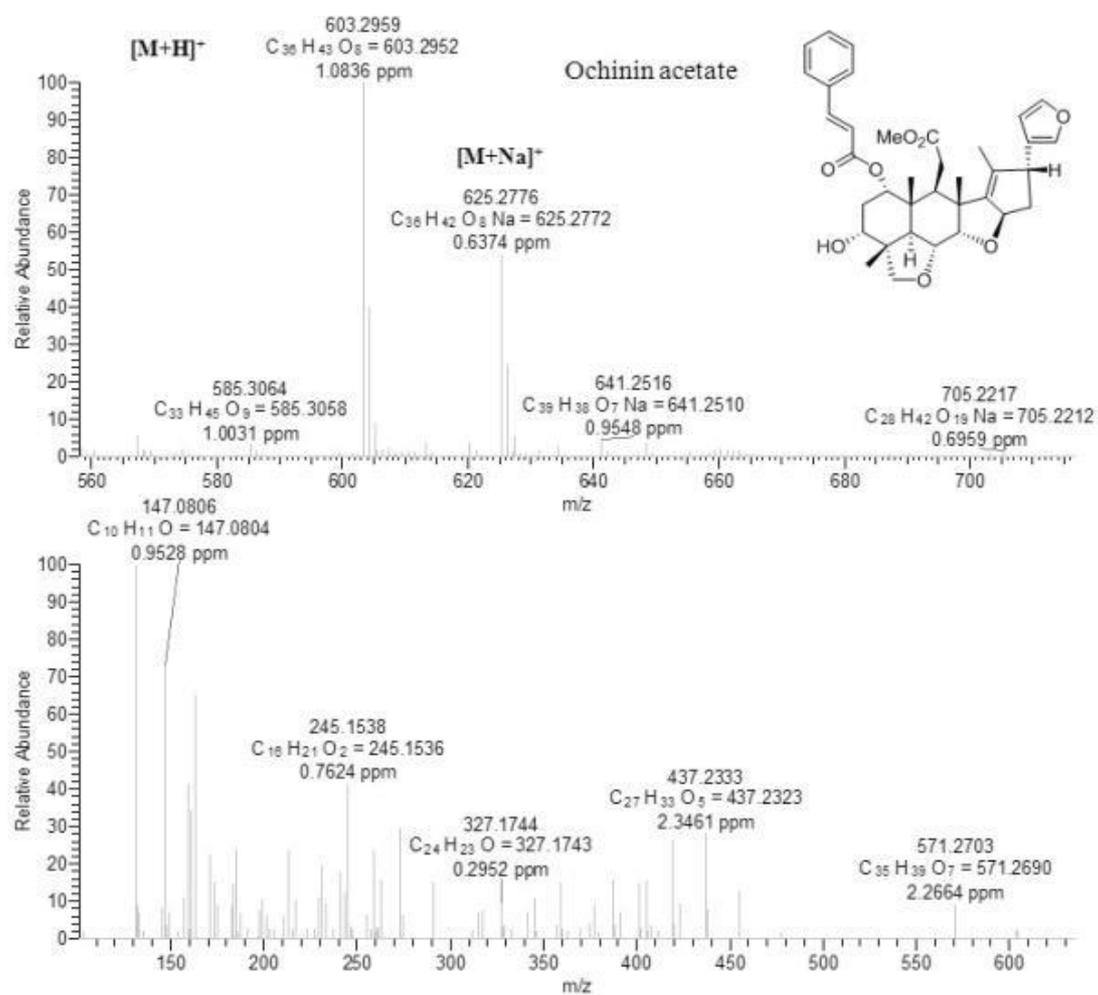

Salannol

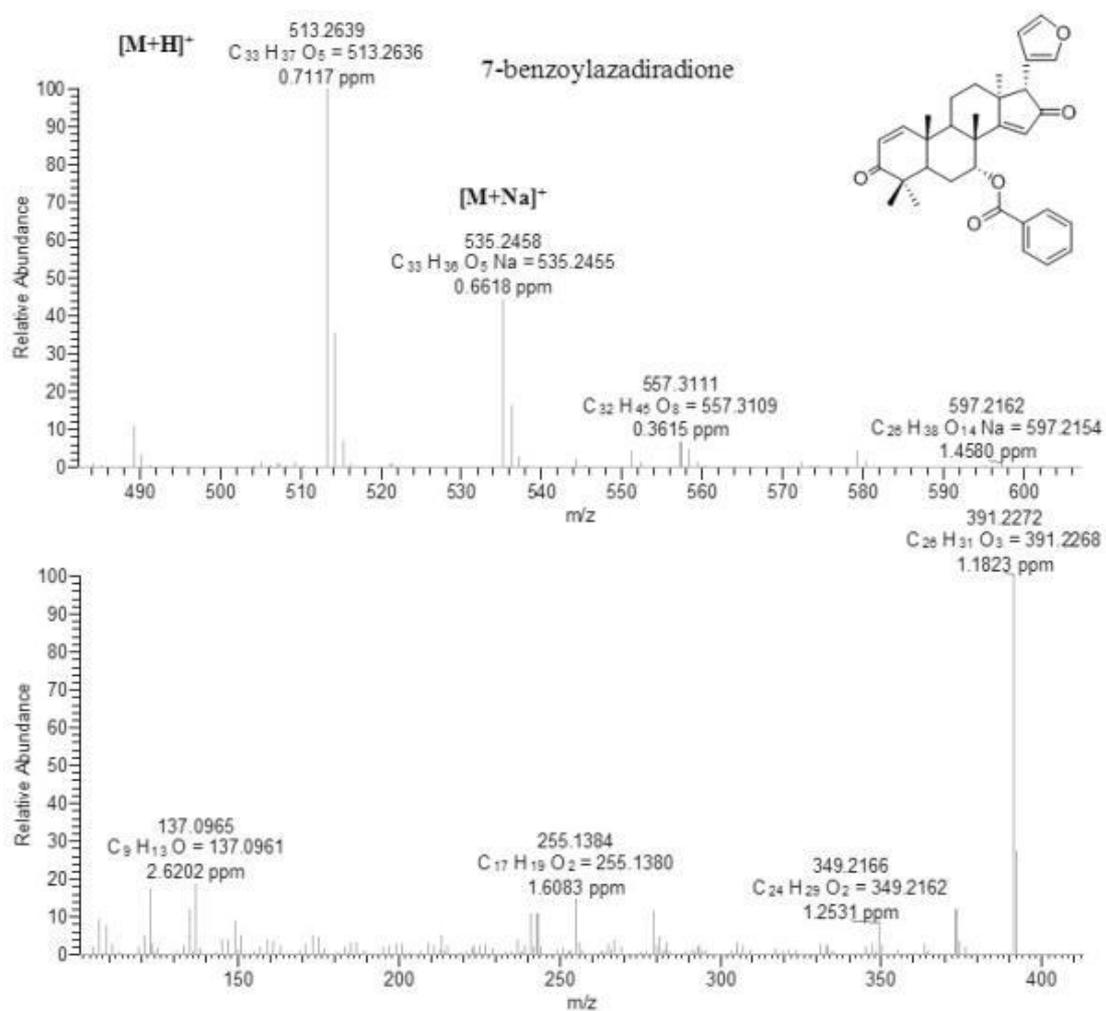

Odoratone

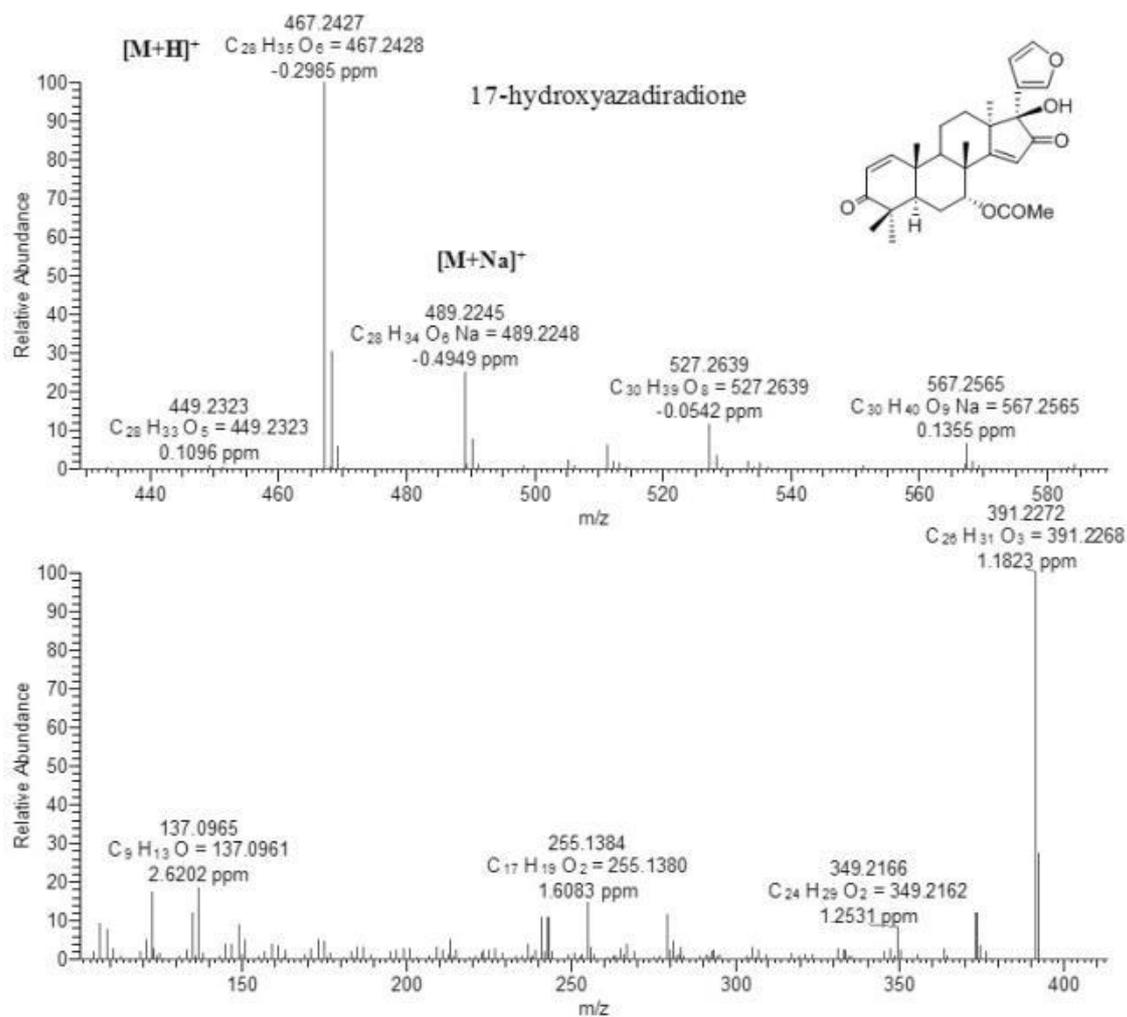

Ochinin acetate

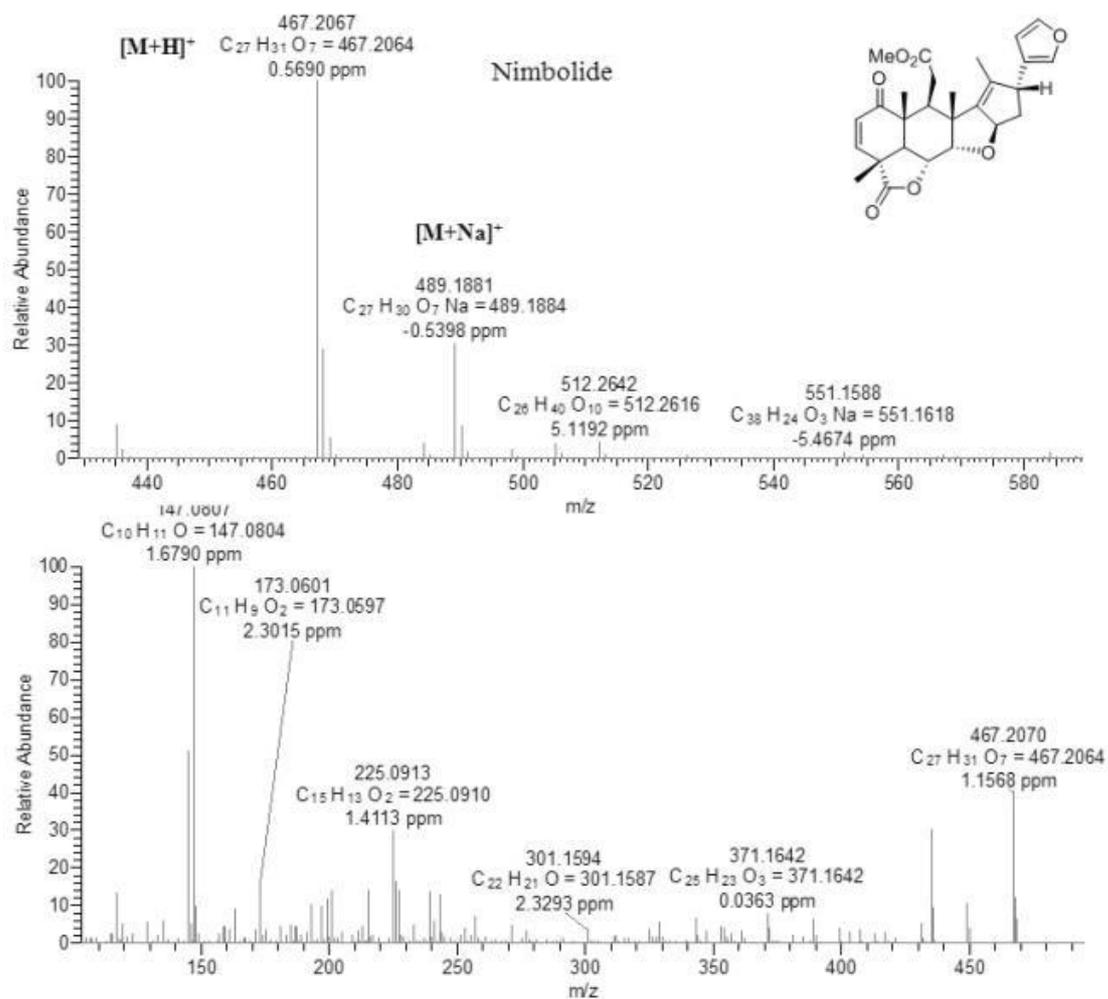

7-benzoylazadiradione

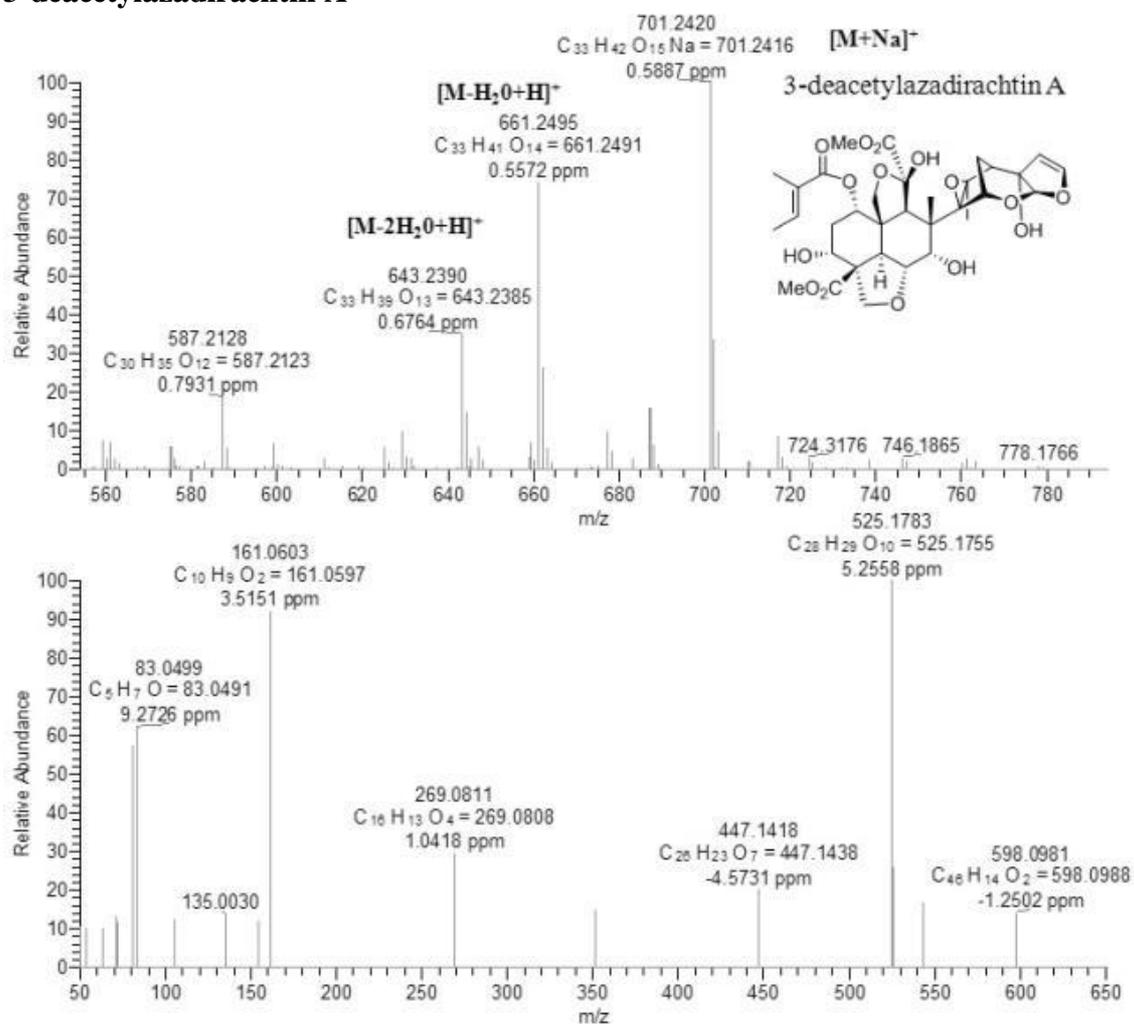

17-hydroxyazadiradione

Nimbolide

3-deacetylazadirachtin A

Salimuzzalin

Chapter 3

Ex vivo tracer study of limonoid biosynthesis in *Azadirachta indica*

Chapter 3: Section A
**Tracing biosynthetic pathways through
stable isotopes - an Introduction**

3A. Introduction

Many of the primary metabolic pathways in the cell have been discovered by isotope labeling which involves tracking the passage of an isotope from reactant to product or through a metabolic pathway (Figure 3A.1) in a cell in *in vivo* or *ex vivo* condition¹. Depending upon the nuclides used for labeling, they are classified as stable and radionuclide labeling. Radioactive labeling helps in deciphering the mechanism of biochemical reactions by monitoring the radioactive label over the reactants and products. It also helps to trace the reaction products in an organism after the introduction of radioactive compound into the organism².

3A.1. Stable isotope labeling

Labeling studies with stable isotopic tracers such as ²H, ¹³C, ¹⁵N have greatly helped in studying the various biosynthetic pathways in living systems². One of famous pathway discovery made in 20th century using stable isotope labeling, which is contributing for the biosynthesis of isoprene units in bacteria, algae, archaea and plants is Methyl-erythritol Phosphate pathway³⁻¹⁰.

3A.2. The discovery of Methyl-erythritol Phosphate pathway

This pathway was discovered accidentally during the study of biosynthesis of bacterial triterpenes, hopanoids by Rohmer and his co-workers^{9, 11-17}. Hopanoids, present in bacterial cell wall are triterpene structures with a C5 side chain. To study the origin of this side chain, labeling experiment was carried out by Rohmer *et al*^{11, 12} with bacteria grown in synthetic mineral media containing acetate as a sole carbon source.

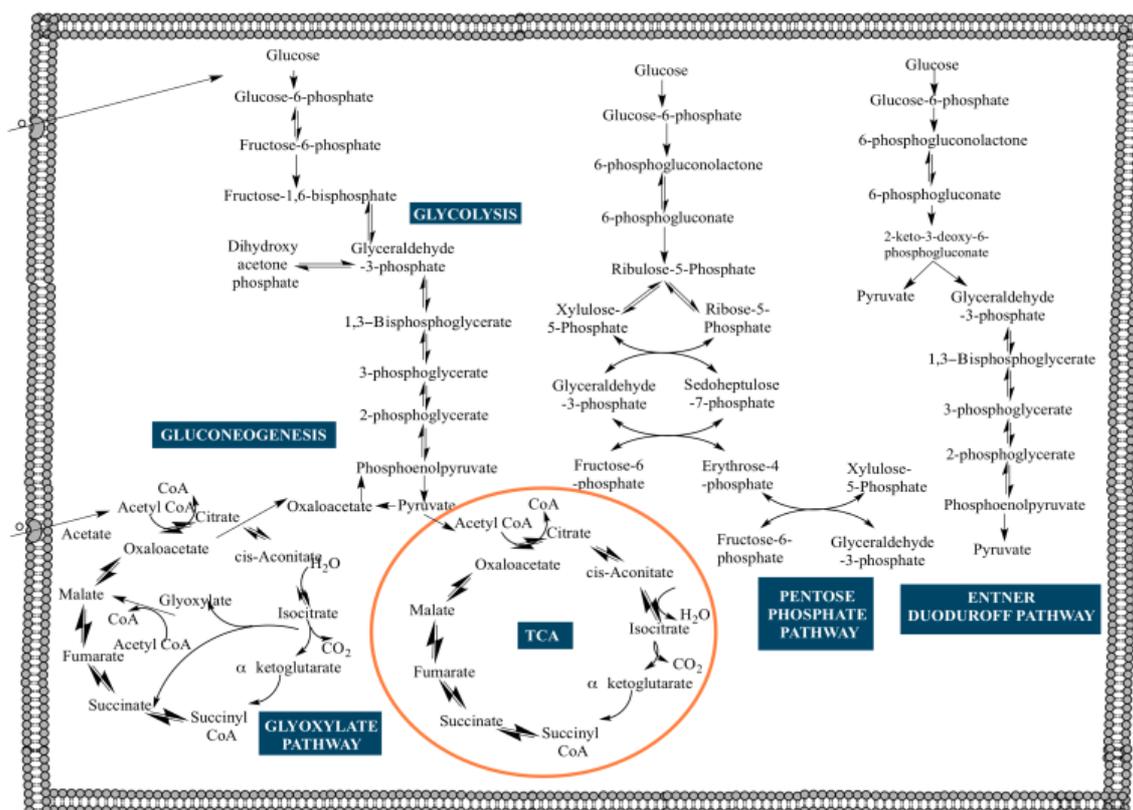

Figure 3A.1. Various pathways in bacteria for utilization of carbon sources such as acetate and glucose

Rhodopseudomonas palustris and *Rhodopseudomonas acidophila*, purple non-sulfur bacteria and the facultative methylotroph *Methylobacterium organophilum* respectively, uses acetate as sole carbon and energy source. They were fed with [1- ^{13}C] acetate and [2- ^{13}C] acetate¹⁵. The labeling pattern of hopanoid showed that the Pentose derived from non-oxidative pentose phosphate pathway is linked *via* its C-5 carbon atom to the hopane isopropyl group (Figure 3A.2). The serendipity observed was that the isoprene units of the triterpenoid skeleton did not correspond to the one as expected through the MVA route (Figure 3A.3). At that time, this contradiction could not be interpreted in the frame that these isoprene units could be synthesized through completely different pathway, as the MVA pathway was strongly believed to be the universal pathway for isoprenoid biosynthesis, although the hypothesis for the existence of different pathway was not completely neglected.

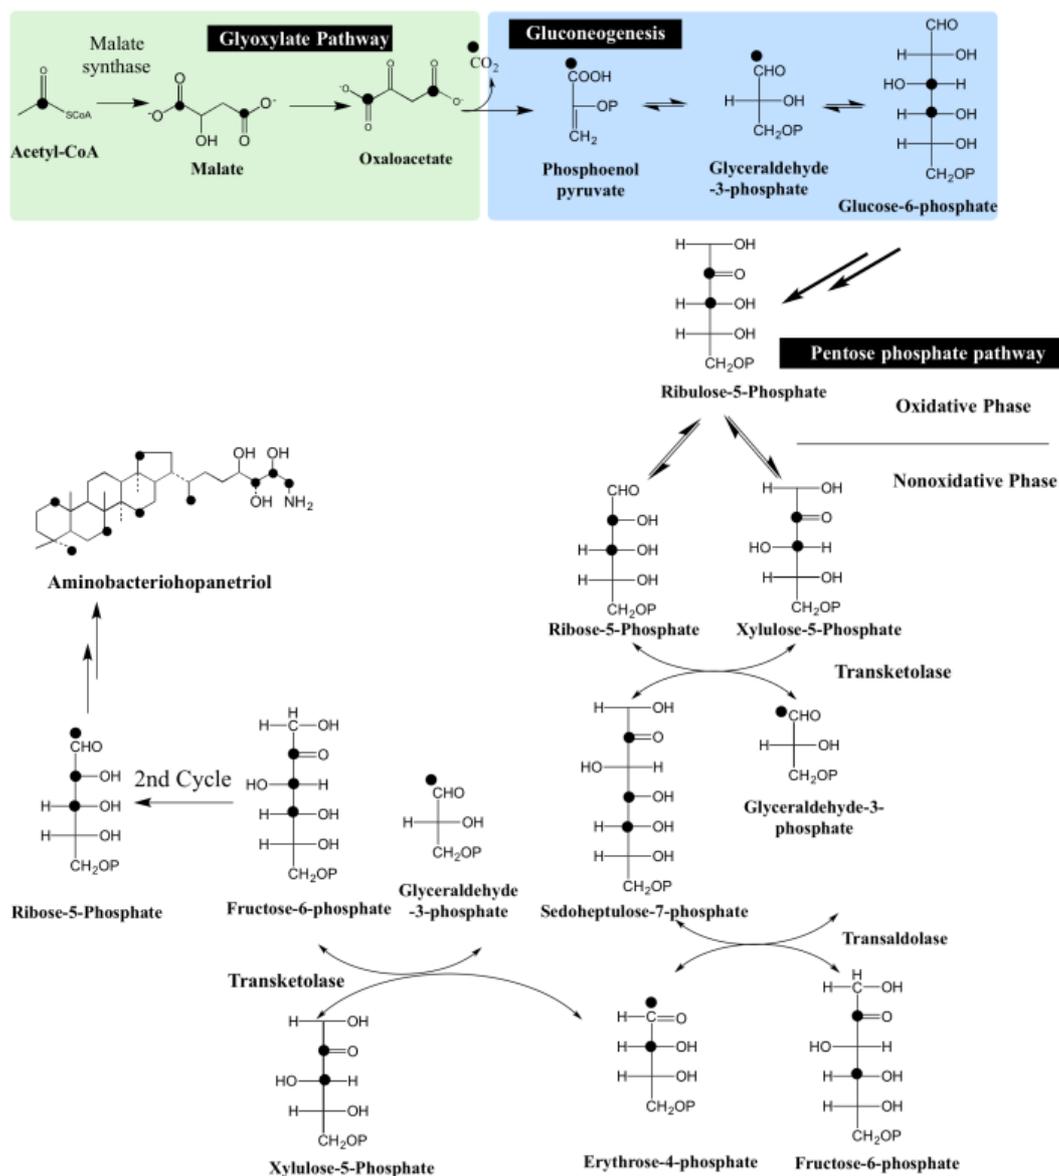

Figure 3A.2. Biosynthetic scheme for the study of formation of 5-carbon side chain of hopanoids through different biosynthetic pathways in bacteria by using labeled $[1-^{13}\text{C}]$ acetate as carbon source.

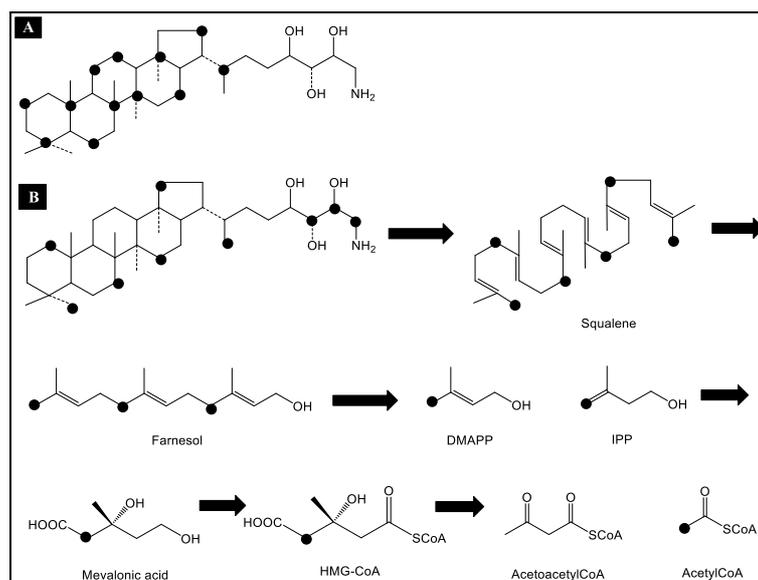

Figure 3A.3. Rohmer's labeling studies with $[1-^{13}\text{C}]$ acetate for the study of hopanoid, aminobacteriohopanetriol from bacteria¹¹. **(A)** Expected labeling pattern of the triterpene skeleton from mevalonate pathway **(B)** Observed labeling pattern of the triterpene skeleton and the deduced retro-biosynthetic scheme based on the pattern

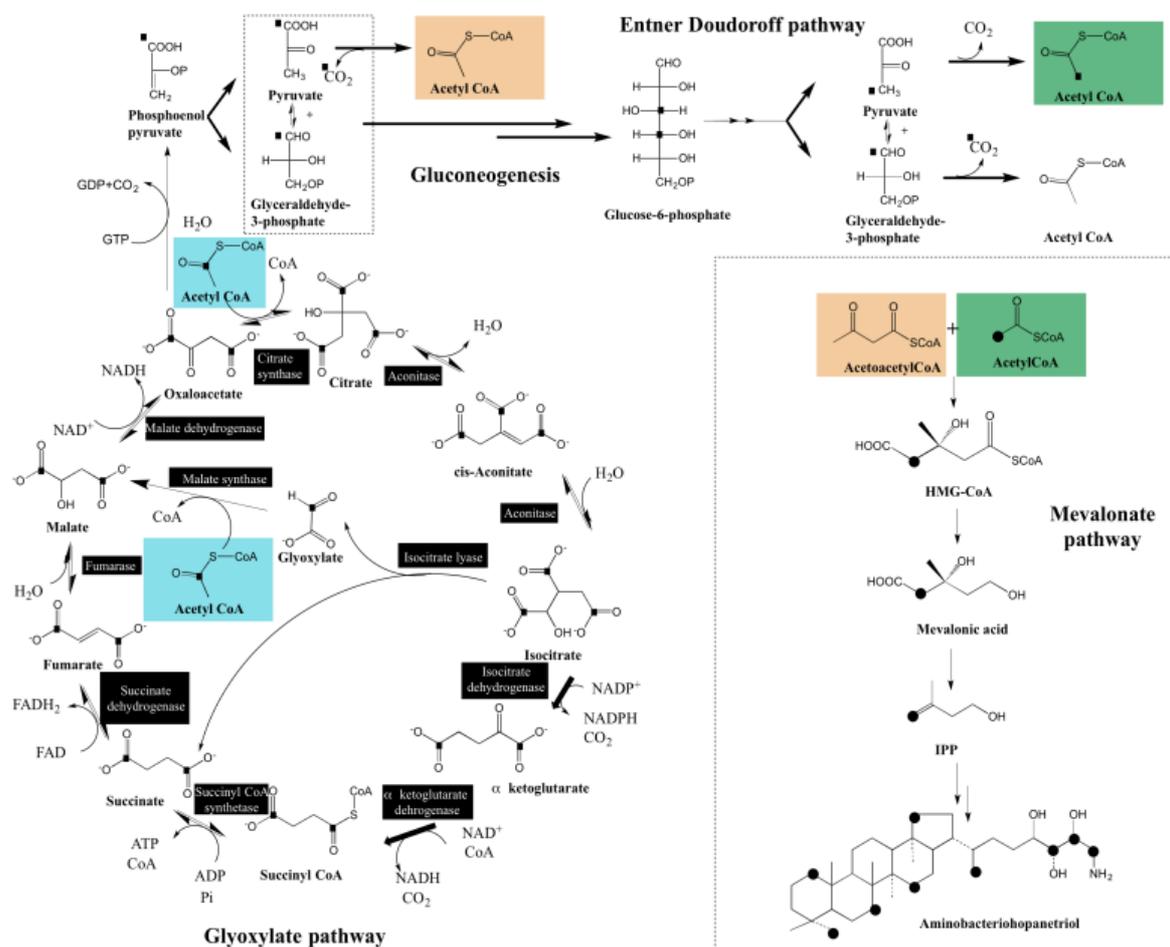

Figure 3A.4. Biosynthetic scheme for the formation of triterpenoid skeleton of hopanoids through alternate biosynthetic pathways in bacteria such as glyoxylate pathway and Entner Doudoroff pathway by utilizing labeled acetate as carbon source¹¹.

From the labeling pattern of hopanoids, it was concluded that MVA had to be formed from two distinct acetyl-CoA pools formed *via* the glyoxylate cycle and the Entner-Doudoroff degradation of glucose (Figure 3A.4)¹¹. This labeling study raised the following problems which has to be resolved at that times: (i) exogenous acetate was not, as expected, directly incorporated into this biosynthetic pathway; (ii) no scrambling of the isotopic enrichment occurred; (iii) the observed labeling patterns differed completely from those expected from the classical isoprenoid-biosynthetic route (MVA pathway)¹¹.

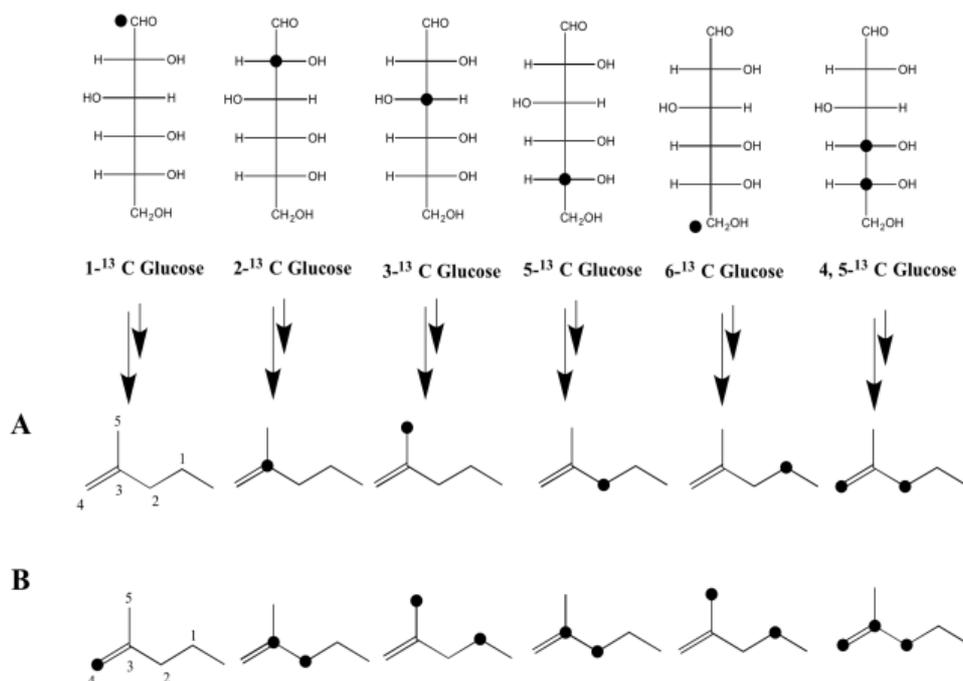

Figure 3A.5. Labeling studies with stable isotope labeled glucose isotopomers and isotopologues carried out by Rohmer *et al.* 1993¹³ with two different bacterium **A.** *Zygomonas mobilis*, **B.** *Methylobacterium fujisawaense*

In his further work, Rohmer used ethanol producing bacterium *Zymomonas mobilis*, which uses hexoses as the only carbon and energy source (Figure 3A.5). *Z. mobilis* was studied for the incorporation of ¹³C-labeled D-glucose labeled at either C-1, C-2, C-3, C-5, C-6 which confirmed that D-ribose derivative is the precursor of the side-

chain of bacteriohopanetetrol¹¹ (Figure 3A.2). In an effort to decipher the origin of carbon atoms in isopentenyl diphosphate biosynthesis, Rohmer¹³ and his co-workers studied the hopanoid biosynthesis in different bacterial species (*Zymomonas mobilis*, *Methylobacterium fujisawaense*, and *Alicyclobacillus acidoterrestris*) which differ in their utilization of carbon source (acetate and glucose) and metabolism (glycolysis, TCA cycle, glyoxylate cycle, Entner-Doudoroff pathway) of their respective carbon source (Figure 3A.1, Figure 3A.9)^{13, 15}. Since, *Escherichia coli* is a poor producer of hopanoids, the incorporation of ¹³C carbon into Ubiquinone was studied. In *M. fujisawaense* and *E. coli*, [1-¹³C] acetate and [2-¹³C] acetate is incorporated into the glyoxylate and tricarboxylic acid cycles, leading to pyruvate and/or phosphoenol pyruvate. *E. coli* metabolized labeled glucose through glycolysis and oxidative pentose phosphate, whereas *M. fujisawaense* utilized glucose via the Entner-Doudoroff pathway (Figure 3A.7, 3A.8)¹⁵. *Z. mobilis* has incomplete TCA cycle and metabolizes glucose through Entner-Doudoroff pathway. *Alicyclobacillus acidoterrestris* utilizes only glucose as carbon source and metabolizes it through glycolysis and oxidative pentose phosphate pathway¹⁵. The labeling pattern in the triterpene skeleton of hopanoids in the above studied organism differed due to utilization of carbon source through different pathway and it determined the origin of carbon atoms of isoprene units^{11, 15}. D-glucose isotopomers labeled at different positions gave a clear distinction in labeling pattern of isoprene units in *Z. mobilis*, which utilizes the Entner-Doudoroff pathway for catabolism of glucose (Figure 3A.9)¹⁵. C-1, C-2 and C-4 of IPP were derived from C-4, C-5 and C-6 of glucose, respectively. C-3 and C-5 of IPP were respectively equally derived from C-2 or C-5 and C-3 or C-6 of glucose¹⁵. Their study produced an opinion that a novel pathway existed for the synthesis of isoprene units. The former studies done by Rohmer *et al.* in hopane series and the one in the later for the incorporation of ¹³C-labeled glycerol or pyruvate into the ubiquinone Q8 of *Escherichia coli* mutants lacking enzymes of the triose phosphate metabolism gave a clear idea that pyruvate as precursor of a C2 subunit and a triose phosphate derivative as precursor of a C3 subunit¹⁴. [1-¹³C] and [6-¹³C] glucose incorporation into ubiquinone in *E. coli* or into the hopanoids in *Alicyclobacillus acidoterrestris* yielded identical labeling patterns with label on all carbon atoms corresponding to C-1 and C-5 of IPP which suggested that the equivalence of carbons C-1, C-2, C-3 of glucose to C-6, C-5, C-4 due to the inter-conversion by triose phosphate isomerase of GAP and DHAP in glycolysis^{11, 13, 15}.

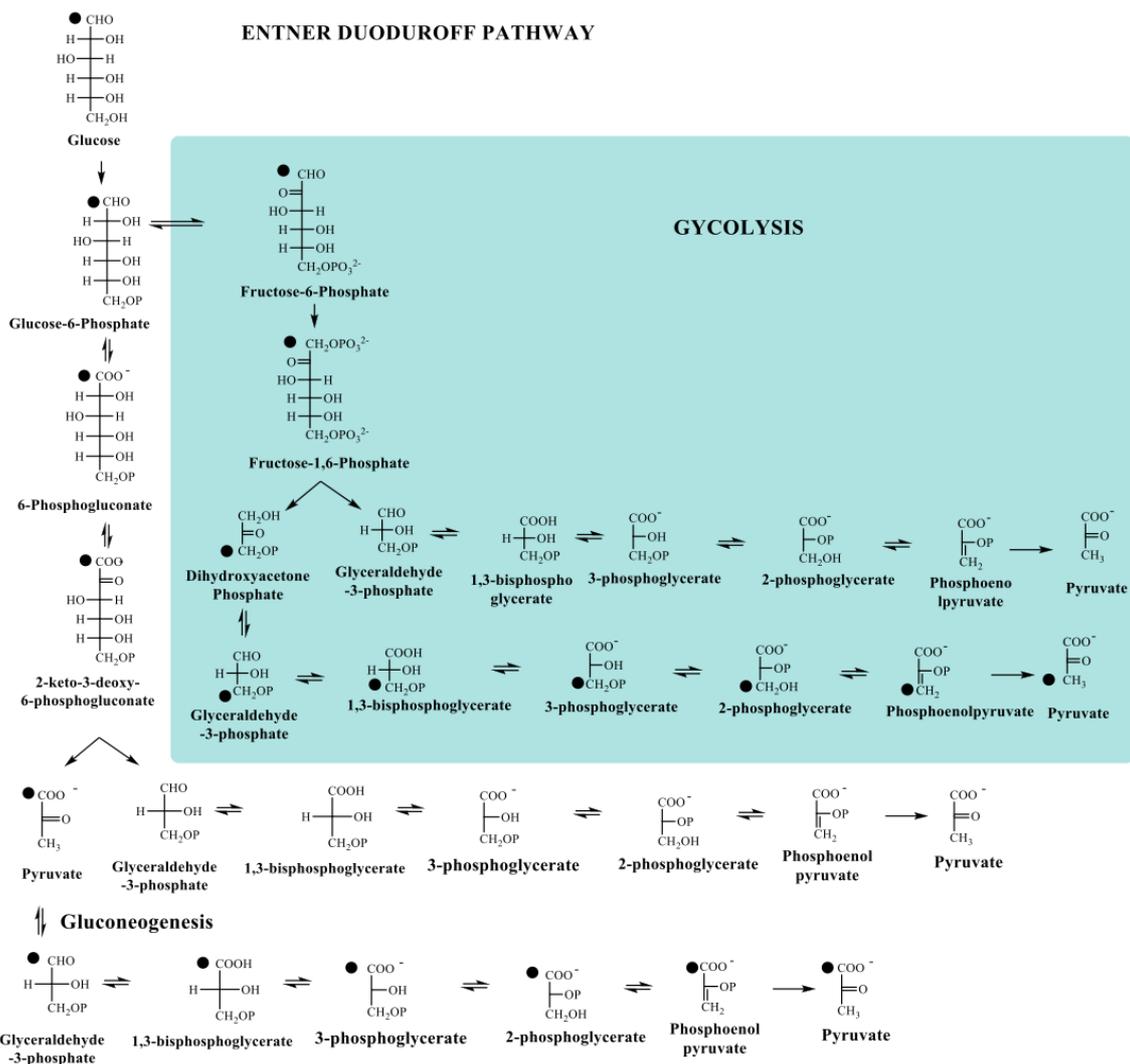

Figure 3A.7. Various pathways such as glycolysis, its alternate Entner-Duoduroff pathway and gluconeogenesis in the cell for glucose metabolism shown through $1\text{-}^{13}\text{C}$ glucose labeling^{12, 13}.

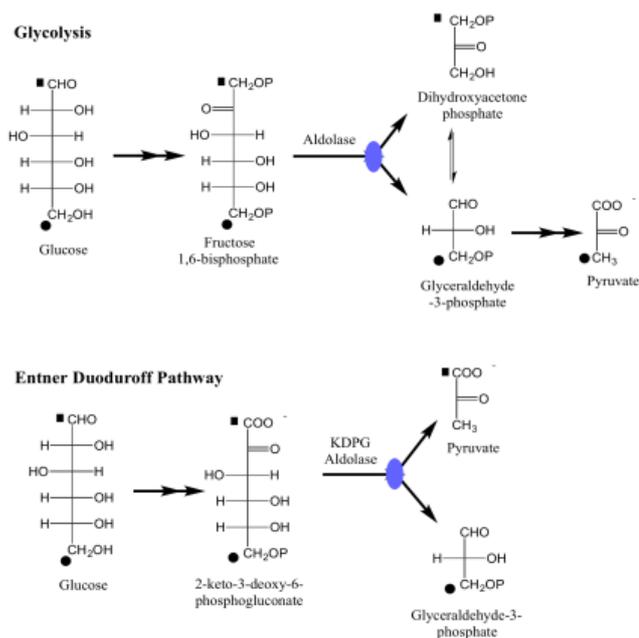

Figure 3A.8. Difference in glycolysis and Entner-Duoduroff pathway present in bacteria in metabolizing glucose into pyruvate^{12, 13}.

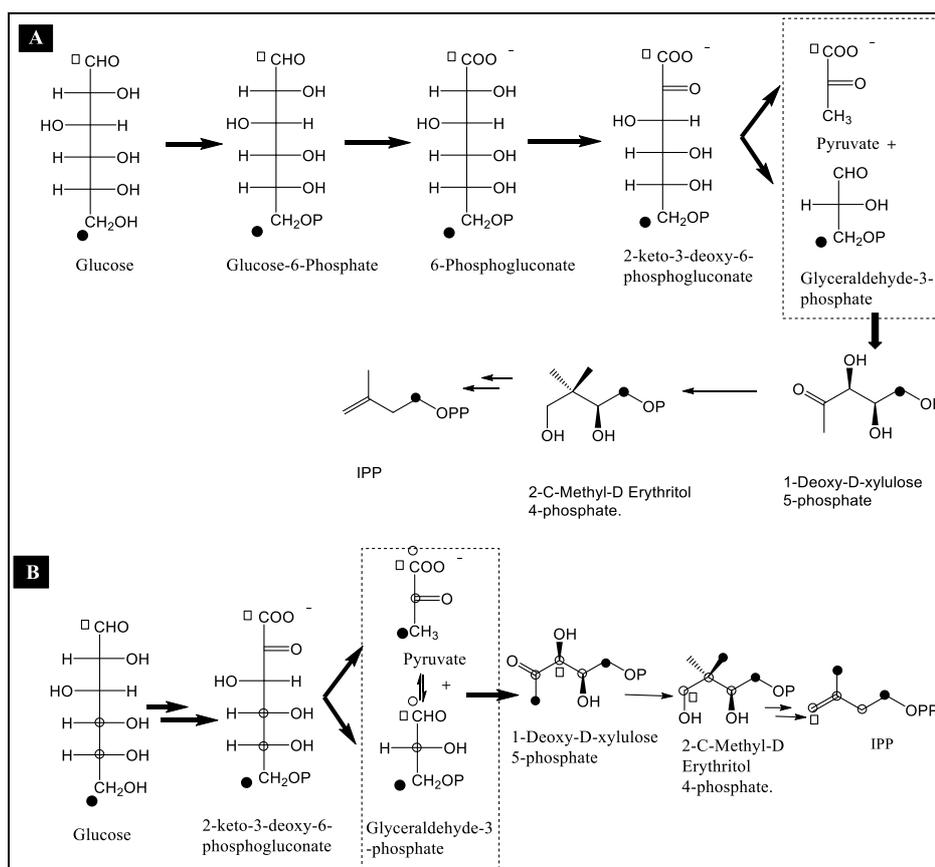

Figure 3A.9. Glucose catabolism via Entner-duoduroff pathway and incorporation of precursors via non-MVA pathway^{12, 13} (A) In *Zymomonas mobilis* (B) In *Methylobacterium fujisawaense* (Filled circle denotes the ¹³C label at 6-C position of glucose, unfilled square denotes label at 1-C whereas unfilled circles denote label at 4,5-¹³C of glucose).

Based on these labeling patterns, mevalonate was not considered as a metabolic intermediate in the newly hypothesized pathway^{12, 13}. MVA, MVA phosphate or MVA diphosphate were not at all incorporated into IPP by cell-free systems in *E. coli* and *Z. mobilis* which gave a clear idea that mevalonate pathway does not exist in most of the prokaryotes. From the identification of non-mevalonate route for isoprenoid biosynthesis through these labeling studies, the search for the existence of either of the pathways in different living systems was initiated^{12, 13}. Labeling studies help in the identification of pathway intermediates, the discovery of new metabolic pathway, precursors of the pathway etc¹⁴.

Chapter 3: Section B
**Establishment of fragmentation pathway for
azadirachtin A through tandem MS**

3B.1. Introduction

The most useful technique available for the labeling studies of metabolite includes mass spectrometry and Nuclear Magnetic Resonance (NMR)^{18, 19}. GC-QTOF, LC-HRMS, capillary electrophoresis mass spectrometry (CE-MS) and Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR-MS) based metabolic profiling acts as a sensitive and reliable method to analyze the metabolite both by qualitative and quantitative means²⁰⁻³⁰. In particular, Isotopic Mass Spectrometry helps in the analysis of isotopologues and isotopomers of molecules². The common hardware platforms available for it includes GC, LC systems²⁷. GC-MS requires derivatization of the sample with reagents such as N-Methyl-N-(trimethylsilyl) trifluoroacetamide (MSTFA) and methoxyamine hydrochloride for the analysis of primary metabolites²⁷. Most of the polar primary and secondary metabolites are resolved and quantified in LC-HRMS as the mass spectral data can be further analyzed using mass spectral alignment tool as it helps to divulge the unknown metabolites in the sample. Tandem mass spectrometry has evolved to be a most powerful technique that allows the cleavage of selected ions into fragment ions, the so-called product ions which helps in understanding the chemical structure of the selected ion (precursor ion)^{31, 32}. Hence, this method helps in screening metabolites, drugs, contaminants in plant, human, environmental samples etc. The fragment ions formed upon cleavage serves as a signature for the identification of that particular metabolite and its derivatives in other samples²⁸. Establishment of structure-fragment relationship uniquely, using different ionization technique such as ESI, APCI, EI etc.³³ helps in further studies such as labeling experiment to trace the position of stable isotopic label present in the same metabolite¹⁸. These techniques also helps in dereplication studies, a process of identification of molecules whose structure is already known and plays an important role in natural product discovery and metabolic pathway analysis^{32, 34}. Establishment of tandem MS fingerprint of novel molecules helps in metabolic pathway discovery of same molecules and also identification of them among complex and diverse mixture of plant natural products³⁵⁻⁴³. Tandem MS fingerprint of ring intact limonoids⁴⁴ and nimbin, nimbinene, salannin type C seco limonoids⁴⁵ have been established earlier based on ESI-MS. Hence, section B of this chapter deals with the chromatographic separation, mass spectrometric characterization, tandem mass spectrometric characterization of 6 natural azadirachtin derivatives purified from neem tree.

3B.2. Results and discussion

3B.2.1. Mass spectrometric characterization of azadirachtin

Azadirachtin A and its derivatives such as 3-deacetylazadirachtin A, azadirachtin B, vepaol, azadirachtin H, 11-epi-azadirachtin D were subjected to UPLC-ESI(+)-quadrupole/orbitrap-MS (Figure 3B.1, 3B.2). Different azadirachtin molecules eluted at different retention times as denoted in Table 3B.1 and the mass spectra of the corresponding molecules showed Na adduct and protonated adducts generated by the loss of one or two H₂O molecules (Figure 3B.2).

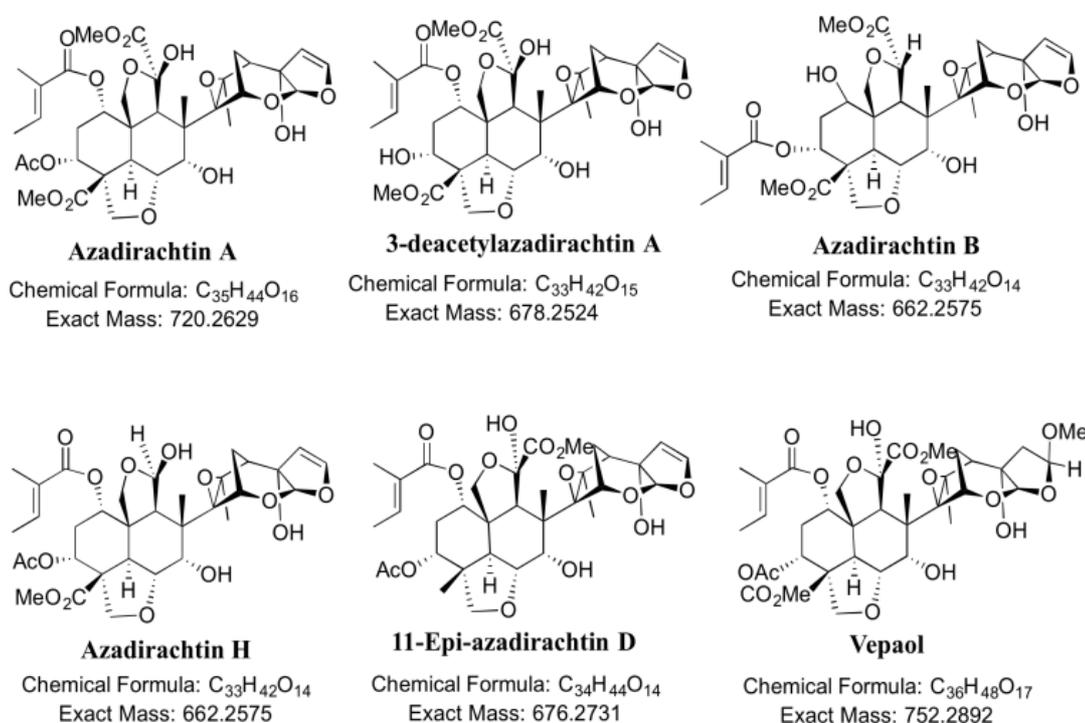

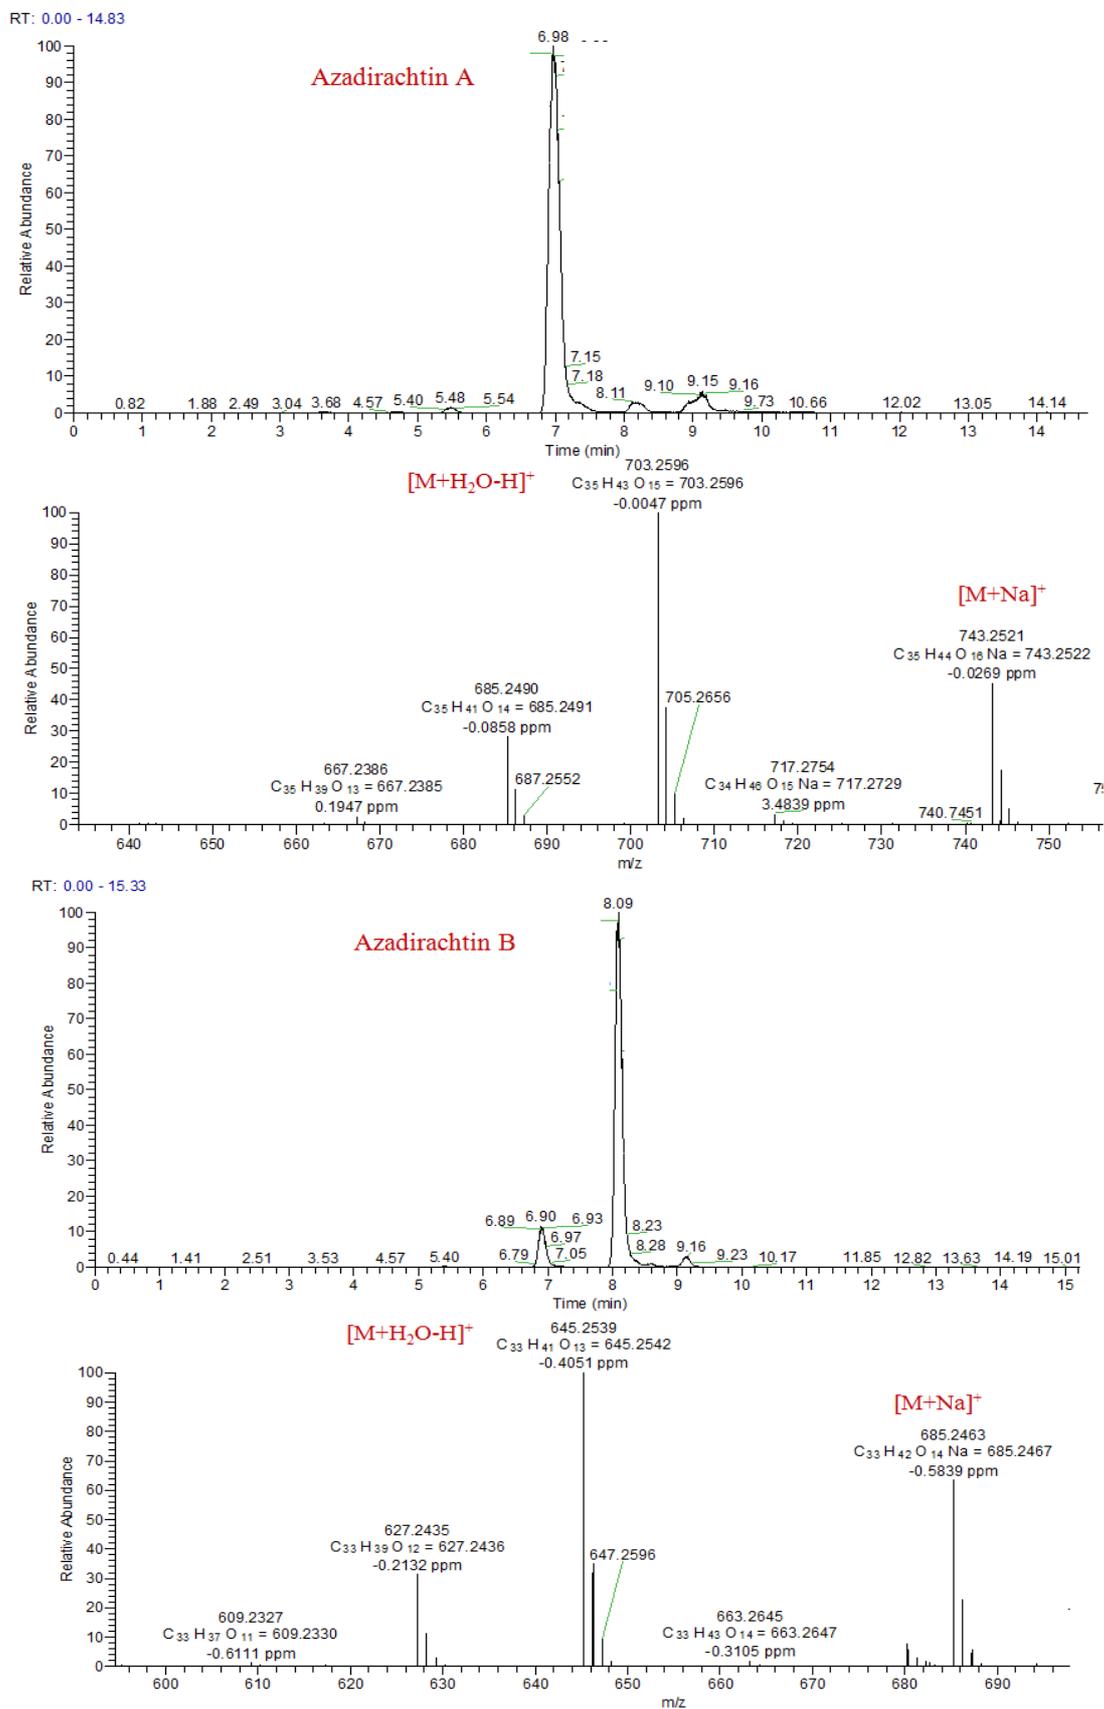

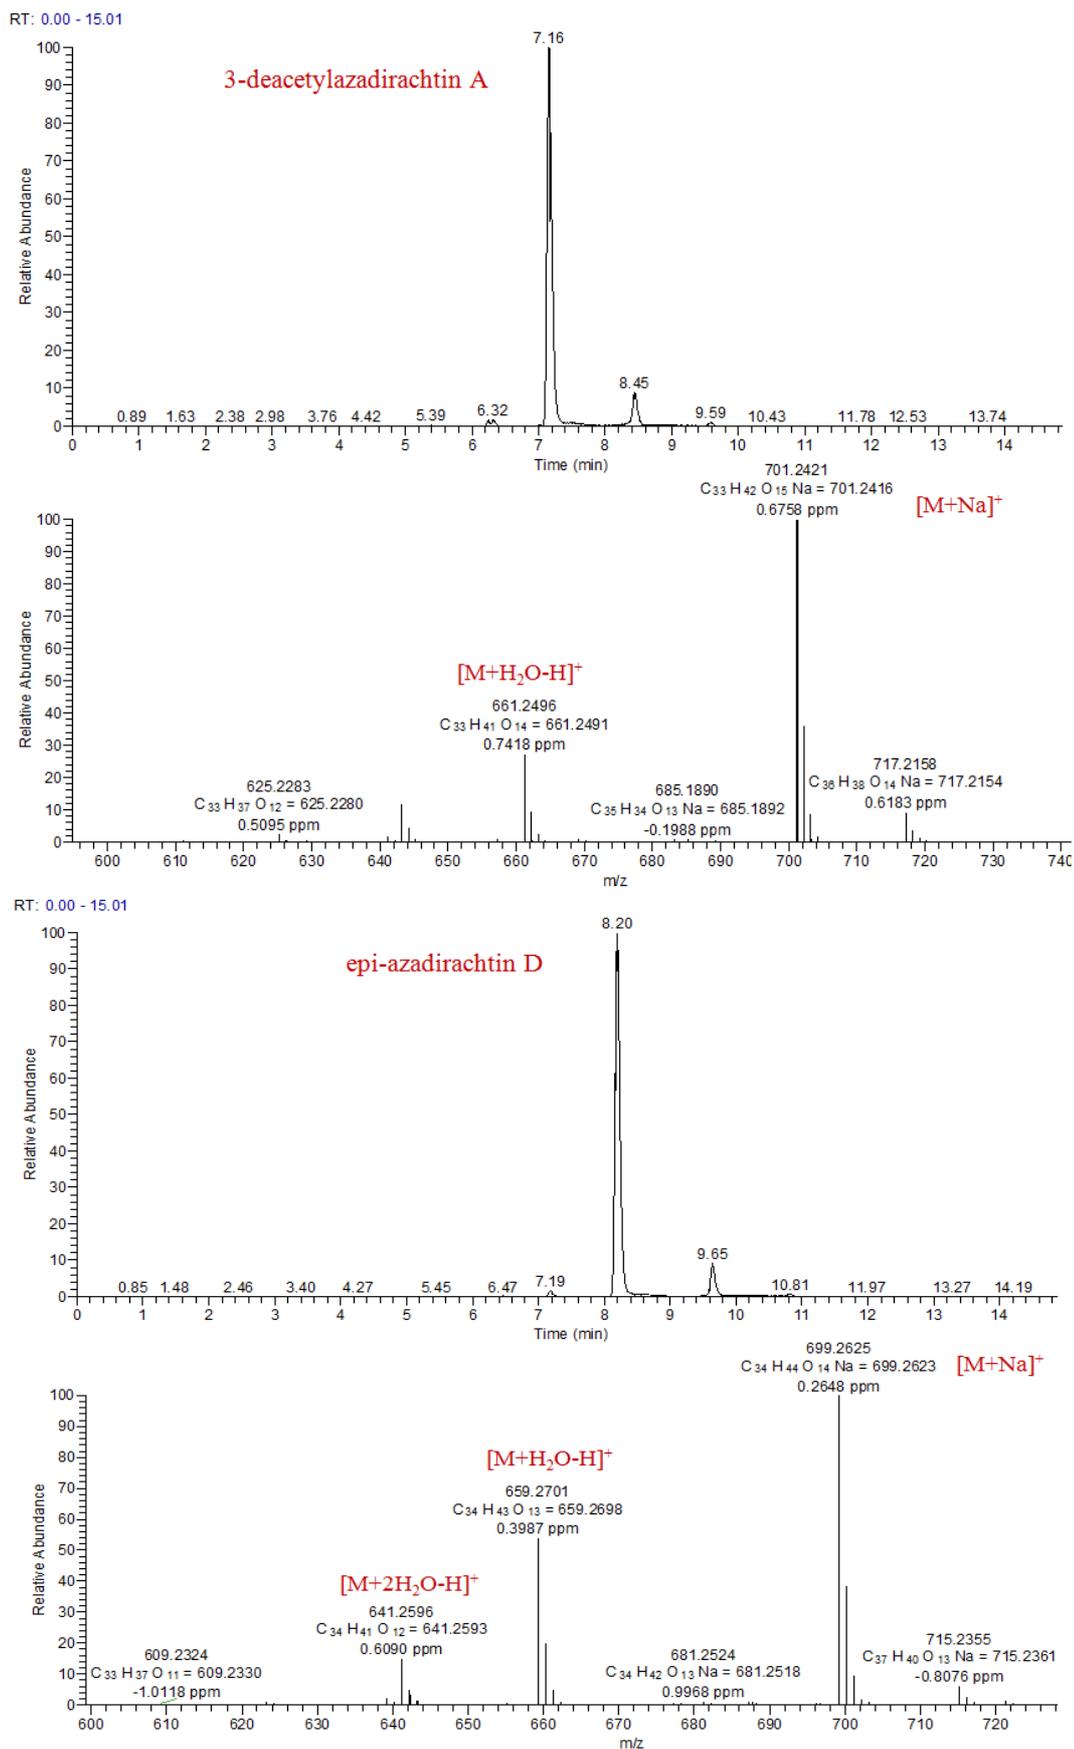

Figure 3B.1. Structures of azadirachtin A and its natural derivatives present in the tree used for comparative analysis

Molecule	Molecular formula	Mass	Molecular ion	<i>m/z</i> of the ion	Retention Time
Azadirachtin A	C ₃₅ H ₄₄ O ₁₆	720.2629	M-H ₂ O+H	703	7
Azadirachtin B	C ₃₃ H ₄₂ O ₁₄	662.2575	M-H ₂ O+H	645	8
Azadirachtin H	C ₃₃ H ₄₂ O ₁₄	662.2575	M-H ₂ O+H	645	6.55
Epi-azadirachtin D	C ₃₄ H ₄₄ O ₁₄	676.2731	M-H ₂ O+H	659	8.2
3-deacetylazadirachtin A	C ₃₃ H ₄₂ O ₁₅	678.2524	M-H ₂ O+H	661	7.16
Vepaol	C ₃₆ H ₄₈ O ₁₇	752.2892	M-H ₂ O+H	735	8.23

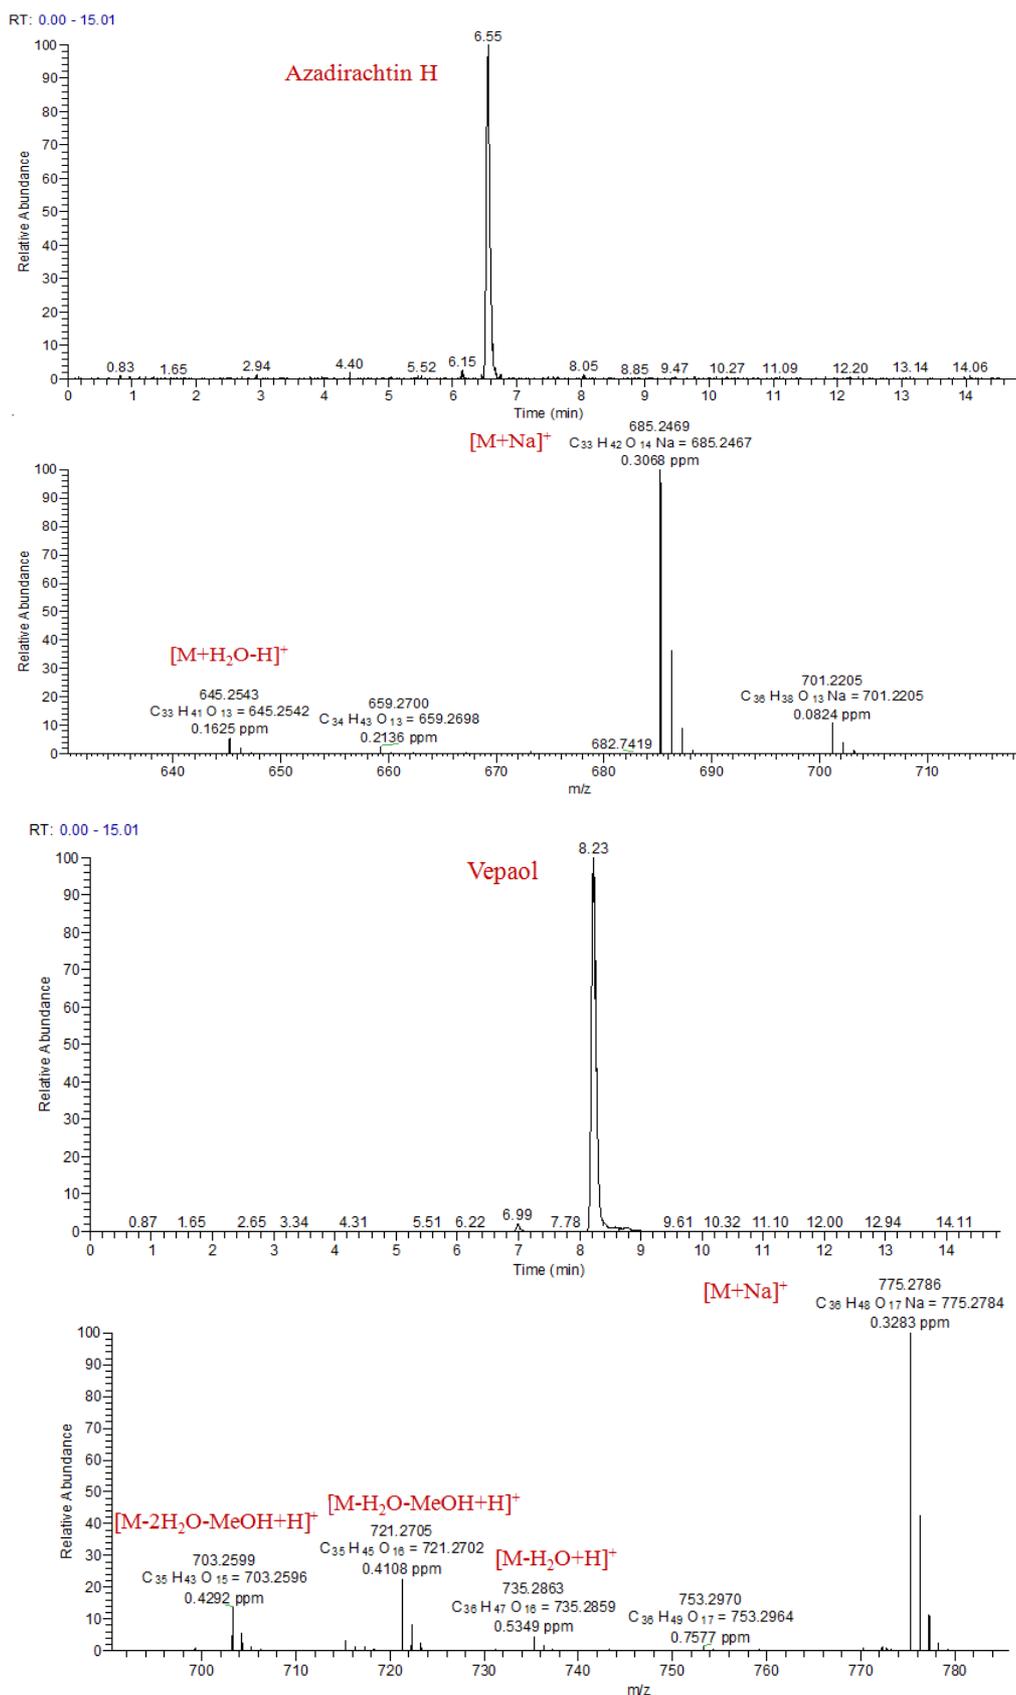

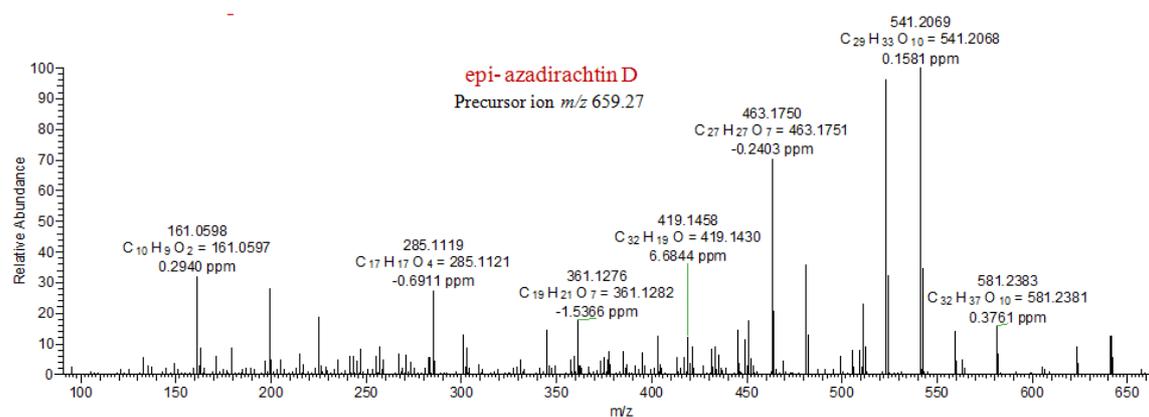

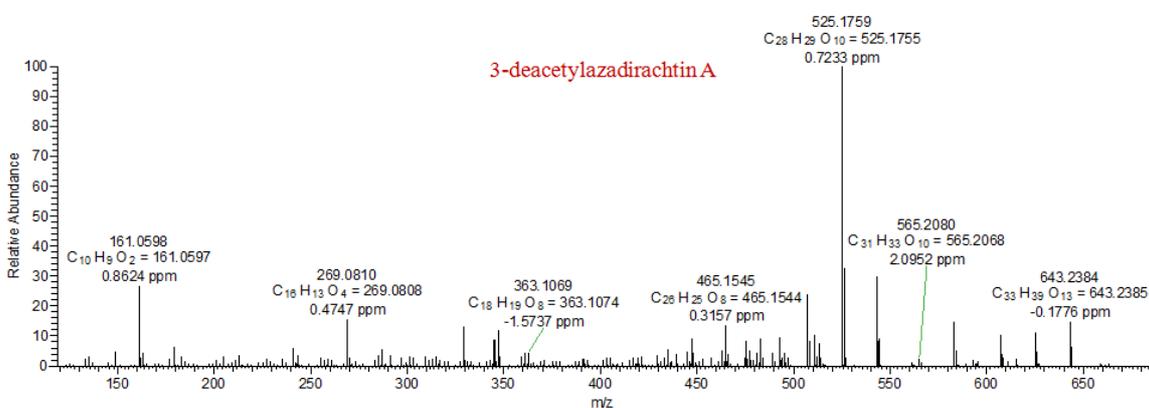

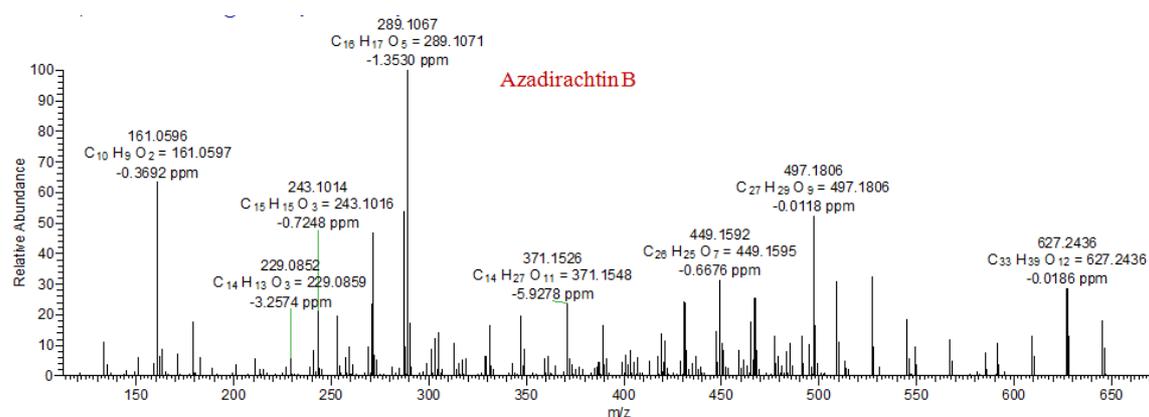

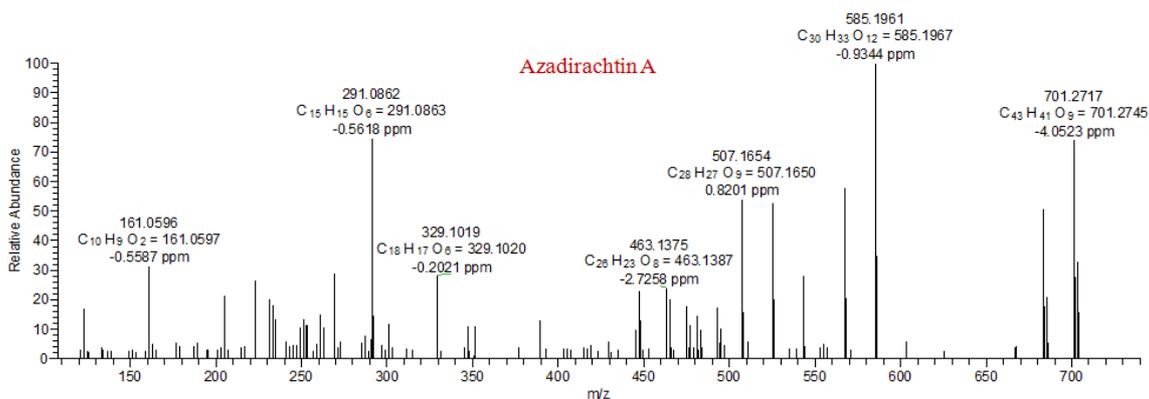

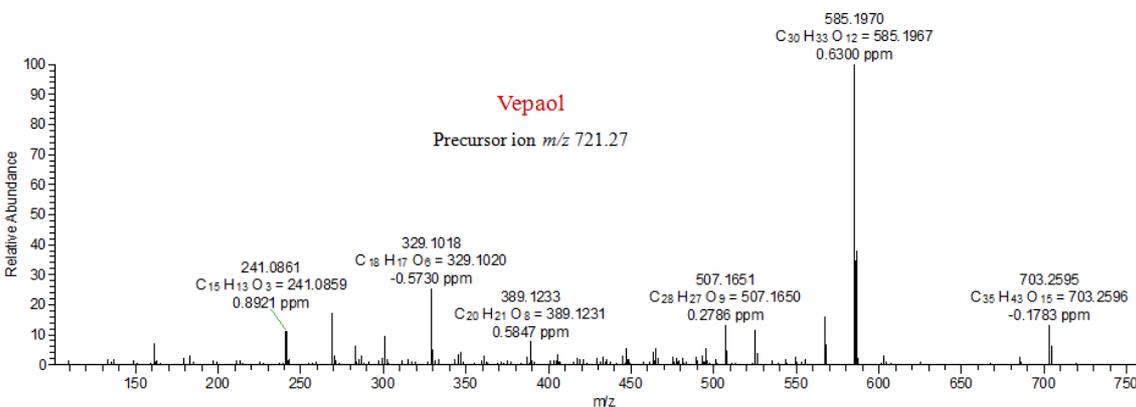

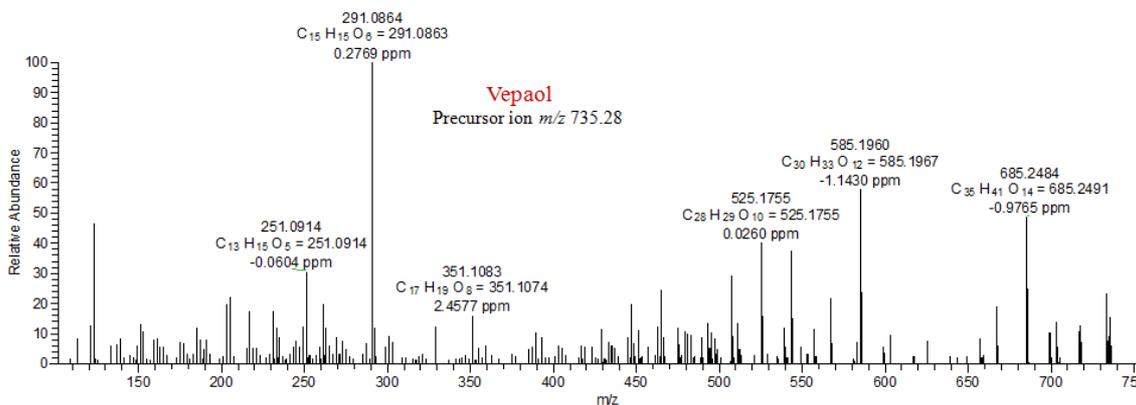

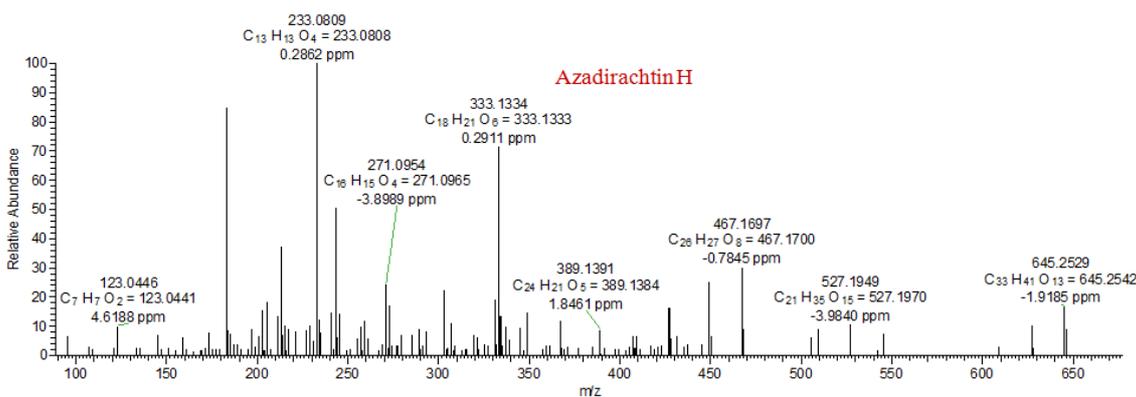

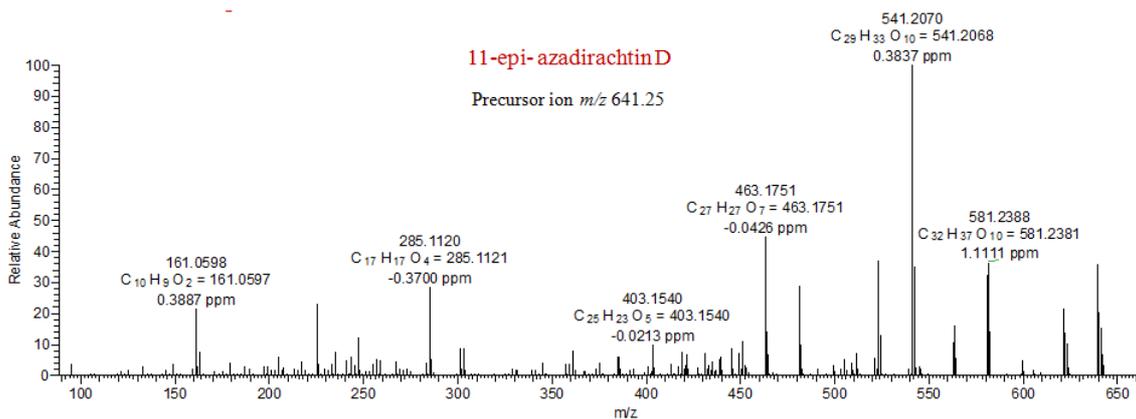

Figure 3B.2. Chromatogram and corresponding mass spectra for six limonoids (Azadirachtin A and its natural derivatives).

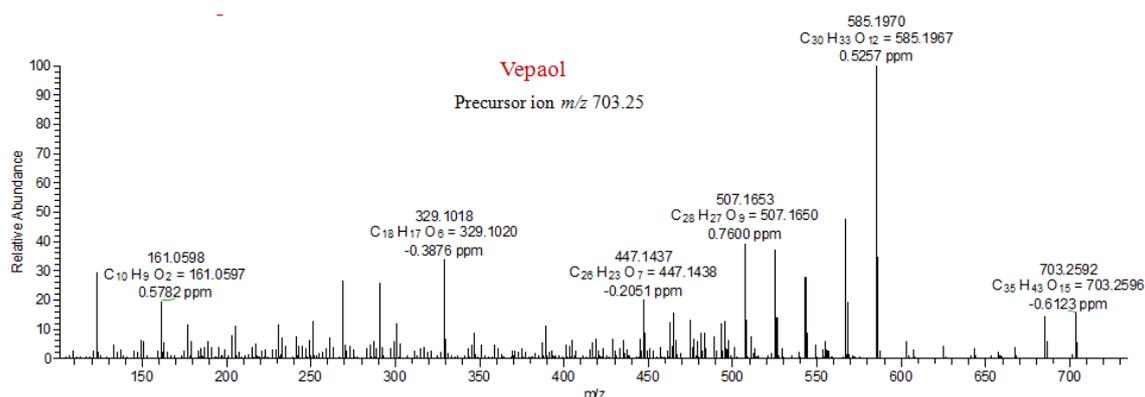

Figure 3B.3. Tandem Mass spectra at (NCE) normalized collision energy of 20% applied to precursor azadirachtin ions generated unique and common product ions among different azadirachtin molecules comparatively.

3B.2.2. Tandem mass spectrometric characterization of azadirachtin A

To understand the fragmentation pattern for azadirachtin A, we have subjected azadirachtin A and its derivatives such as 3-deacetylazadirachtin A, azadirachtin B, vepaol, azadirachtin H, 11-epi-azadirachtin D to UPLC-ESI(+)-quadrupole/orbitrap-MS/MS study. Mass spectral traces of azadirachtin A and its derivatives did not show molecular ion peak ($[M+H]^+$) however had the fragment ion with a loss of water molecule, i.e. $[M-H_2O+H]^+$ and sodium adduct $[M+Na]^+$. $[M-H_2O+H]^+$ adduct was considered as parent ion and was subjected to MS/MS fragmentation at various NCEs such as 10%, 15%, 20% and 25% (Figure 3B.4). At 20% NCE, both the high and low molecular weight fragments were equally distributed in intensity and hence used to understand the fragmentation pattern for azadirachtin. The signature spectral fragments (daughter ions) obtained after fragmentation of each azadirachtin derivative at 20% NCE and their corresponding relative intensity have been populated in the table (Table 3B.2).

Probable fragmentation pathway for the formation of daughter ions of azadirachtin A, when the parent ion, $[M-H_2O+H]^+$ m/z 703.2596 was subjected to MS/MS at the NCE of 20% has been schematically represented (Figure 3B.5). The mass fragmentation of parent molecular ion, m/z 703.2596, lead to the formation of fragment m/z 685.2491 $[M-2H_2O+H]^+$, due to loss of a molecule of H_2O and it was identified at the relative intensity of 2.6%. This fragment m/z 685.2491, undergoes several neutral losses to generate fragments in the high molecular range at m/z 625.2280 $[M-2H_2O-AcOH+H]^+$ (3.2%), 607.2174 $[M-3H_2O-AcOH+H]^+$ (1.2%), 585.1967 $[M-2H_2O-Tiglic\ acid+H]^+$, 567.1861 $[M-3H_2O-Tiglic\ acid+H]^+$ (62.2%), 525.1755 $[M-2H_2O-Tiglic\ acid-AcOH+H]^+$ (30.4%),

and 507.1650 [M-3H₂O-Tiglic acid-AcOH+H]⁺ (85.6%). Hydrolysis of one of the ester group and/or removal of one or two CH₂O molecules from *m/z* 507.1650 gave rise to the fragments *m/z* 493.1493 [M-3H₂O-Tiglic acid-AcOH-CH₃+H]⁺ (15%), 463.1387 [M-3H₂O-Tiglic acid-AcOH-CH₂O-CH₃+H] (28.9%) and 447.1438 [M-3H₂O-Tiglic acid-AcOH-2CH₂O+H]⁺ (50%), respectively. A low relative ion intensity (13%) fragment of *m/z* 555.1861 [M-2H₂O-Tiglic acid-CH₂O+H]⁺ was formed after removal of a H₂O, tiglic acid and a CH₂O group from the parent ion.

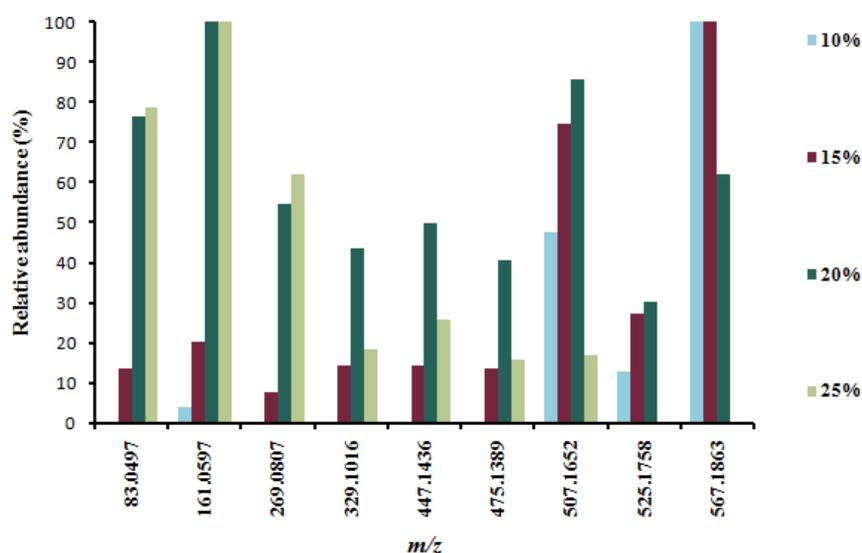

Figure 3B.4. Variation in relative abundance of MS/MS daughter ions obtained at varying normalized collision energies (NCEs) 10, 15, 20, 25% for azadirachtin A.

The lower molecular weight fragments of *m/z* 329.1020 and *m/z* 269.0808 corresponded to the decalin portion (A and B ring) of azadirachtin molecule formed after the detachment of hydrofuran acetal moiety from the fragments *m/z* 507.1650 and *m/z* 447.1438 respectively. Finally, the hydrofuran acetal moiety of azadirachtin was identified as fragment of *m/z* 161.0597 with highest intensity of 100%. The fragments of *m/z* 400 to 600 range were possibly formed through protonation-mediated cleavage of tigloyl ester bond and thereby release of tiglolate daughter ion (*m/z* 83.0491) with 76.4% intensity. This was in line with the fragmentation pattern obtained with salannin and 3-deacetylsalannin molecules.

3-deacetylazadirachtin A molecule differs from azadirachtin A by the absence of acetyl group at 3-C of ring A. The parental molecular ion, *m/z* 661.2491 [M-H₂O+H]⁺ was subjected to fragmentation at NCE of 20% and each daughter fragment obtained

were probed for its molecular formula and corresponding structure. The daughter ions, m/z 643.2382 $[M-2H_2O+H]^+$, 625.2281 $[M-3H_2O+H]^+$ and 607.2174 $[M-4H_2O+H]^+$ were obtained after successive removal of H_2O molecules following protonation. Fragments such as m/z 525.1758, 507.1655, 465.1543, 447.1436 and 329.1013 obtained were in common with azadirachtin A fragmentation pattern (Table 3B.2).

Vepaol possesses a methoxy group in the hydrofuran moiety of azadirachtin A, thereby contributing to the increase in molecular weight of 32 Da. Mass spectra of vepaol showed the presence of three protonated ion peaks with m/z 735.2867, 721.2705, and 703.2598 which are formed through removal of either H_2O molecule or methoxy group or both (Table 3B.2). All these three parental ions were subjected to fragmentation at NCE 20% and the resulting daughter ions for each of them were studied. Most of the daughter fragments of azadirachtin A were observed in common with vepaol, as it possess same structure of azadirachtin A after the removal of methoxy group (Table 3B.2).

Azadirachtin B is devoid of hydroxyl group at 11-C, tiglate at 1-C and 3-C acetyl functionality is replaced with tiglate group in comparison to azadirachtin A. The removal of tiglate moiety from the parent ion m/z 645.2542 ($[M-H_2O+H]^+$) yielded the fragment m/z 545.2017 $[M-H_2O-Tiglic\ acid+H]^+$. The fragments, m/z 509.1806 $[M-3H_2O-Tiglic\ acid-AcOH+H]^+$, 527.1912 $[M-2H_2O-Tiglic\ acid-AcOH+H]^+$ and 271.0965 obtained were on par with m/z 507.1650, m/z 525.1755 and m/z 269.0809 of azadirachtin A, respectively (Figure 3B.5, Table 3B.2) due to the absence of double bond between 9-C and 11-C.

Azadirachtin H is a decarboxymethyl derivative of azadirachtin A at 11-C position and MS/MS at NCE 20% fragmented the parent ion to greater extent such that only lower m/z fragments formed from decalin portion were seen (Table 3B.2). Higher mass fragments such as m/z 545.2017 $[M-H_2O-Tiglic\ acid+H]^+$, 509.1806 $[M-3H_2O-Tiglic\ acid+H]^+$, 467.1700 $[M-2H_2O-Tiglic\ acid-AcOH+H]^+$ and 449.1595 $[M-3H_2O-Tiglic\ acid-AcOH+H]^+$ were obtained at $\leq 15\%$ NCE.

11-epi-azadirachtin D lacks one of the two methylester groups of azadirachtin A and produced two types of protonated ions with m/z 659.2704 $[M-H_2O+H]^+$ and 641.2598 $[M-2H_2O+H]^+$. The following fragments m/z 285.1121 and 345.1333 were formed from the decalin portion of the molecule (Table 3B.2). The subsequent removal of the functional groups such as hydroxyl, tigloyl, acetyl groups generated fragments

such as m/z 541.2068 [M-2H₂O-Tiglic acid+H]⁺, 523.1963 [M-3H₂O-Tiglic acid+H]⁺, 481.1857 [M-2H₂O-Tiglic acid-AcOH+H]⁺, 463.1751 [M-3H₂O-Tiglic acid-AcOH+H]⁺, m/z 451.1751 [M-2H₂O-Tiglic acid-AcOH-CH₂O+H]⁺ from both the parent ions.

The fragment m/z 161.0597 was identified in fragmentation pattern of most of the azadirachtin derivatives. The fragments, m/z 161.0597 and m/z 83.0491 corresponds to hydrofuran acetal moiety and tiglate group. Therefore either one acts as a signature fragment for azadirachtin class of limonoids from neem tree.

Therefore, structure-fragment relationship of azadirachtin A, thus obtained will not only help to infer the position of ¹³C labels incorporated into it, but also serves as a sensitive method for identification of azadirachtin in environmental as well as biological samples. We have studied already, the structure-fragment relationship for C-seco limonoids such as salannin, salannolacetate, nimbin, nimbinene, 6-deacetylnimbinene and 6-deacetylnimbin, isolated and purified from neem oil⁴⁵. These results have been used for deducing the pattern of ¹³C incorporation into the same limonoids and their isotopologues identified in our feeding experiments.

Molecule	Precursor ion (m/z)	Molecular formula of precursor ion	Adduct	Daughter ion m/z (formula, Relative intensity) at NCE 20%

Table 3B.2. Azadirachtin derivatives, precursor ion, MS/MS daughter ions and intensity of fragments obtained from fragmentation of the precursor ion at 20% NCE.

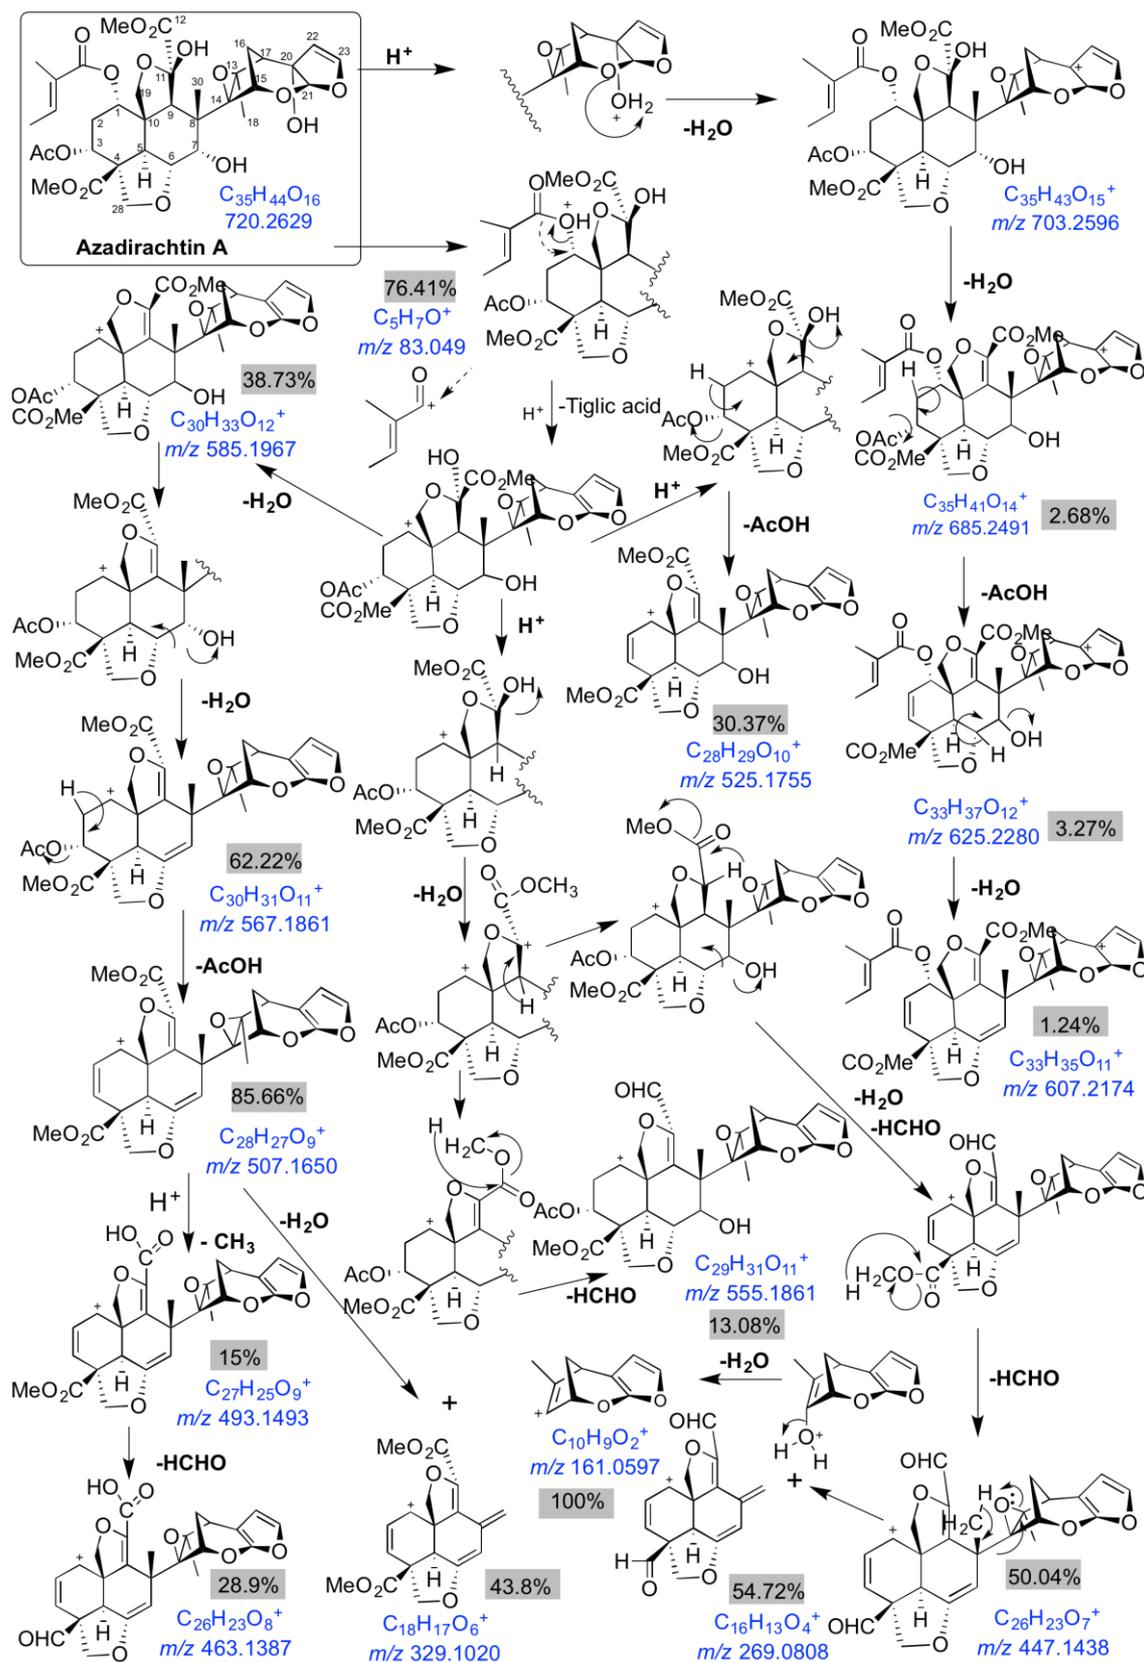

Figure 3B.5. The structure-fragment relationship of azadirachtin A was inferred from the tandem MS fragmentation studies of five azadirachtin derivatives at various NCEs based on which the putative fragmentation pathway of azadirachtin A was extrapolated.

3B.3. Conclusion

The structure fragment relationship of azadirachtin A was established based on the fragmentation pattern of azadirachtin A and its derivatives. This will help to identify and quantify azadirachtin in biomedical or environmental samples. The structure fragment relationship also helps further for the identification of the position of ^{13}C labels into the metabolite biosynthesized *in vivo* by uptake of labeled precursors in cell culture.

3B.4. Materials and methods

3B.4.1. Establishment of structure-fragment relationship for azadirachtin A

To establish the structure-fragment relationship for azadirachtin A, derivatives of azadirachtin such as azadirachtin B, 11-epi-azadirachtin D, azadirachtin H, 3-deacetylazadirachtin A, vepaol isolated and purified from neem seeds were subjected to MS/MS at various NCEs such as 10%, 15%, 20% and 25%. Based on the comparison of structure of different molecules of azadirachtin and their respective fragmentation pattern comprising of fragments from higher to lower m/z values, the structure of each fragment obtained after fragmentation of azadirachtin A molecule was established.

3B.4.2. LC-ESI-Mass Spectrometry conditions

Analysis of neem limonoids was performed with Thermo Scientific QExactiveTM hybrid quadrupole-Orbitrap mass spectrometer associated with Accela 1250 pump and Accela open AS. The conditions of HESI source include capillary temperature of 320 °C, Heater temperature at 350 °C, s-lens RF level of 50, Spray voltage of 3.6 kV, spray current of 0.9 μA with sheath gas flow rate of 41, Auxiliary gas flow rate of 9 and sweep gas flow rate of 3. Standards, as well as the extracted samples, were analyzed in positive ionization mode, in full MS-scan with scan range of 100 to 1000 m/z . Following were the properties of the scan performed- resolution 70,000, AGC target 1e6, Maximum IT 200 ms. Waters Acquity UPLC BEH C18 column (particle size 1.7 μm , 2.1 X 100 mm) was used as the stationary phase while the solvent system of methanol and water containing 0.1% formic acid served as the mobile phase. The gradient started with 40% methanol (5 min isocratic), it was then increased to 50% (5 min isocratic), followed by 60% methanol for the next 15 minutes and over the next 4 minutes it was isocratic with 65% methanol. It was then increased to 90% methanol for 4 minutes. For the last 2 minutes, it was isocratic with 40% methanol. Constant flow rate of 0.3 mL min^{-1} was

maintained throughout the run time of 35 min. The chromatograms and mass spectral data were processed by Xcalibur qual browser (version 2.3; Thermo Scientific).

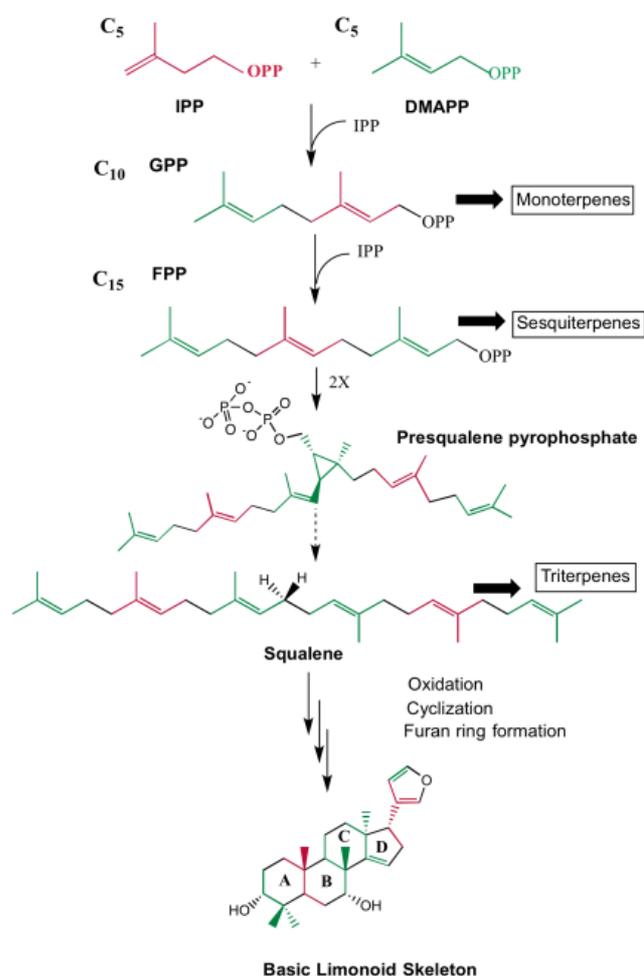

Chapter 3: Section C

**Tracing the biosynthetic origin of limonoids
and their functional groups through stable
isotope labeling in neem cell suspension**

3C.1. Introduction

In higher plants, biosynthesis of isoprenoids occurs through either of the two biosynthetic pathways: mevalonate pathway (MVA) or the methyl-erythritol phosphate pathway (MEP) or through a combination of both pathways⁴⁶⁻⁴⁸. MVA pathway is localized in the cytosol of the plant cell,⁴⁷ whereas MEP pathway occurs in the plastids⁴⁸⁻⁵⁰. It is found that monoterpenes, diterpenes and tetraterpenes are synthesized through the plastidic MEP pathway^{51, 52} and sesquiterpenes, sterols (triterpenes) through the cytosolic MVA pathway, however it varies between plants and under different physiological conditions⁵³⁻⁵⁵. Contradictory to this prevalence of dichotomy, there are evidence based on labeling studies that suggest the differential contribution of isoprene C5 units from either of the two pathways towards the biosynthesis of different metabolites due to traversing of isoprene units across the thylakoid membrane of plastids^{53, 56-59}. In neem tree, tetracyclic triterpene skeletal intermediate(s), en route to the formation of proto-limonoids through successive oxidation and rearrangement reactions⁶⁰. The proto-limonoid further undergoes skeletal rearrangements and functionalization mediated by oxido-reductase and hydrolase enzyme systems to form higher limonoids such as basic and C-seco limonoids⁶⁰. Depending on the skeletal modifications, limonoids can be subdivided into ring-intact (basic) and C-seco limonoids (Figure 3C.1B). Ring-intact limonoids encompass 4,4,8-trimethyl-17-furanylsteroidal skeleton such as Azadiradione and its derivatives. C-seco limonoids are generated by C-ring opening and further rearrangements thus producing nimbin, salannin and azadirachtins type of limonoids (Figure 3C.1)^{61, 62}. Although intensive work has been carried out on the isolation, characterization, synthesis and bioactivity of limonoids, a very little is known about their biosynthesis and remains as a fact of speculation hitherto.

3C.1.1. Isoprenoid biosynthesis in various living systems

Isoprenoid precursors are synthesized only through mevalonate pathway in archaea, fungi and animals⁶³. However, in the case of bacteria, there exists plasticity in which few use only mevalonate pathway, while other pathogenic bacteria use MEP pathway, which serves as the metabolic target for most anti-infective drugs⁶⁴⁻⁶⁶. Some

bacteria utilize both pathways for the biosynthesis of isoprenoids, while some parasitic species lack both the pathways as they depend on the hosts for obtaining isoprenoid precursors⁶⁴⁻⁶⁶. Soon after the discovery of MEP pathway in bacteria, distribution of non-mevalonate pathway among different living organisms was intriguing and remained as a problem⁶⁷. Specific inhibitors of the pathways⁶⁸ and labeled precursors were expected to be useful tools to address this unsolved issue. Experiments were performed by various research groups in different organisms to elucidate the pathway for biosynthesis of isoprene units^{56-58, 69-87}.

3C.1.1.1. Isoprenoid biosynthesis in bacteria

The MEP pathway is responsible for the biosynthesis of terpenoids in a number of eubacteria based on the number of labeling studies conducted by Rohmer and co-workers, whereas methanogenic archaea were found to generate terpenoids via the mevalonate pathway⁶⁷. In addition to hopanoids of several bacteria, ubiquinone of *E. coli* was found to be synthesized through non-mevalonate pathway based on the evidence of incorporation of ¹³C labeled deoxyxylulose into ubiquinone⁸⁸ and deuterium labeled methyl-erythritol into ubiquinone and menaquinone⁸⁹. Contradictory to these studies, menaquinone and naphtherin produced by *Streptomyces aeriouvisifer* showed the simultaneous operation of mevalonate and non-mevalonate pathways for isoprene biosynthesis⁹⁰. The green phototrophic eubacterium, *Chloroflexus aurantiacus* was also known to use mevalonate pathway for the biosynthesis of diterpene verrucosan-2 β -ol⁹¹. The mevalonate pathway was observed only in sulfate-reducing, methanogenic, and hetero fermentative lactic acid bacteria⁶⁷.

3C.1.1.2. Isoprenoid biosynthesis in algae

The first successful experiments were performed with the green alga *Scenedesmus obliquus*⁹². From the study, the only existence of non-mevalonate pathway was obvious by investigation of biosynthesis of all plastidic isoprenoids (prenyl side chains of chlorophylls, plastoquinone-9, β -carotene and lutein) and cytoplasmic sterols through ¹³C labeled acetate and glucose catabolism^{48, 85, 92-95}. To find the involvement of either of the pathway in other species of algae, Rohmer and his co-workers conducted feeding experiments with [1-¹³C] glucose which resulted in the evidence that only MEP pathway operates for the biosynthesis of all isoprenoids in green algae *Chlorella fusca* and

*Chlamydomonas reinhardtii*⁹³. The red alga *Cyanidium caldarium* and the Chrysophyte, *Ochromonas danica* used the MVA route for synthesis of sterols, whereas chloroplast isoprenoids were synthesized via MEP route⁴⁸. Euglenophyte, *Euglena gracilis* exclusively used MVA route for biosynthesis of all isoprenoids, whereas cyanobacterium *Synechocystis* PCC used MEP route⁹³. Although, it was supposed that eukaryotic photosynthetic organisms possessing MVA pathway have acquired plastids as endosymbionts during the course of evolution, in algae only MEP pathway exists for the biosynthesis of all isoprenoids^{63, 96, 97}. Chlorophyta encompassing classes of green algae was found to use MEP pathway for the synthesis of not only the plastidic, but also the cytosolic isoprenoids⁹⁵. Charophyceae, which are the close relatives to the land plants and green flagellate, *Mesostigma viride* showed dichotomy as in plants: plastidic isoprenoids through MEP pathway and cytosolic through MVA pathway⁹⁵.

3C.1.1.3. Isoprenoid biosynthesis in plant system

The first evidence for the existence of MEP pathway in plant system was provided by Schwarz in an independent feeding experiment with ¹³C labeled glucose for the study of ginkgolides and bilobalides which gave a same pattern of labeling as that found in bacteria utilizing glucose through glycolysis at the same instance of identification of this novel pathway in bacteria¹⁵. The labeling methods which proved successful for bacteria, were utilized for plant systems, which were grown heterotrophically with a single ¹³C labeled carbon source under low light intensities that is not conducive for photosynthesis but allowed differentiation of chloroplasts for the study of the synthesis of pigments formed from isoprene units⁹⁸. This condition has prevented the scrambling of the label from ¹³CO₂ obtained from the catabolism of the labeled carbon source as ¹³CO₂ could be refixed through the Calvin cycle during photosynthesis⁹⁸. Taxol, a diterpene from *Taxus chinensis* was demonstrated to be biosynthesized through non-mevalonate route in 1996⁷⁶. Soon after the identification of alternative pathway for the biosynthesis of isoprenoids in bacteria and algae, Rohmer in collaboration with Lichtenthaler investigated various isoprenoids in plant system (*Daucus carota*, *Lemna gibba* and *Hordeum vulgare*) using [1-¹³C] glucose feeding which showed the same novel labeling pattern as found in bacteria and algae, in chloroplast bound isoprenoids such as phytol, plastoquinone, carotene and lutein, whereas, labeling pattern according to MVA was obtained in sterols^{48, 85, 92-95}. These results gave a reasonable interpretation that the novel

alternative pathway must be plastid bound and therefore plants possess two pathways for isoprenoid biosynthesis. To substantiate these findings, the same group conducted feeding experiments with 1-[²H] deoxy-D-xylulose in various higher plants *Populus nigra*, *Chelidonium majus*, and *Salix viminalis* and algae, which produced isoprene and phytol with the deuterium incorporation⁴⁸. Thus, studies on many other plant systems have been taken up by different groups to investigate the distribution of the pathways in plants for synthesis of different metabolites. Biosynthesis of basic isoprene units and their contribution to the final products of mono-, di-, tri-, tetraterpenoid origin were brought to light by individual research groups by examining the position and distribution of labels on the products obtained through labeled precursors, which was used to reconstruct the pathways and mechanisms^{3, 86, 98-102}. Bryophytes, the primitive plants also showed a clear dichotomy as observed in plants, which was evident from various studies for biosynthesis of sesquiterpenes, diterpenes, triterpenes in liverworts^{77, 80, 103}. These studies in higher plants concluded that, biosynthesis of isoprenoid precursor, isopentenyl diphosphate (IPP) occurred through both mevalonate and non-mevalonate MEP pathway, but were highly compartmentalized. This compartmentation was identified in plants in 1967 by Goodwin and his co-workers before elucidation of the plastidic Rohmer pathway, based on the impermeability of the proffered ¹⁴C-mevalonate into plastids, which showed the preferential labeling of ubiquinone and sterols but not the carotenoids whereas ¹⁴CO₂ being incorporated into all isoprenoids¹⁰⁴. In previous studies, Goodwin could find the incorporation of ¹⁴C-mevalonate into plastidic isoprenoids in intact chloroplasts¹⁰⁵⁻¹⁰⁷, which was later found to vary depending on plastid development stages¹⁰⁸.

3C.1.2. Tracing Isoprenoid biosynthesis by *in vivo* labeling

Tracer studies using potential precursors labeled with radioactive or stable isotopes are among the most important methods for elucidating the biosynthetic pathways and mechanisms leading to natural products^{109, 110}. Transfer of the labeled precursors into its products is used to reconstruct the pathways and mechanisms by considering the position and distribution of the labels^{109, 110}. The history of the study of isoprenoid biosynthesis right from the identification of mevalonate pathway⁴⁶ in 1950s till the discovery of MEP pathway in 1990s have deeply recorded unanimously the role played by labeled precursors in identification of the intermediates of the metabolic pathways. In

the beginning, radioactive precursors such as ^{14}C -labeled acetate and mevalonic acid have played a major role in elucidating the biochemical pathways of steroids¹¹¹, which was later replaced by stable isotope labeled precursors during the elucidation of Rohmer pathway due to its feasibility by improvement in mass spectrometry and NMR technology (review by Groeneveld and Bacher)^{109, 111}. The elucidation of cholesterol biosynthesis in mammals was one of the first applications of isotope labeling in biochemistry^{112, 113}.

Soon, after the identification of MEP Pathway in prokaryotes, the intermediates of the pathway were identified by various isotope labeled compounds¹⁰. Deuterium labeling of pathway specific precursors have helped in complete elucidation of the pathway intermediates^{7, 86}. Fates of the hydrogen atoms of 1-deoxyxylulose in its conversion to ubiquinone in *E. coli*⁸⁸. Further, stable isotope-labeled (^{13}C and deuterium), pathway-specific precursors, 1-deoxy-deoxylulose and mevalolactone were used to trace the origin of isoprene units through either of the two pathways. Dual biosynthetic pathway to phytosterol was brought out by Ohyama *et al.* using deuterium and ^{13}C -labeling of the precursor mevalonate, which differentiated the phytosterol synthesized through the intermediates lanosterol and cycloartenol⁸⁶. The essentiality of intramolecular rearrangement in pentulose for obtaining isoprene unit was proved from the quadruple-labeled isotopomers [1,2,3,4- $^{13}\text{C}_4$]-IPP obtained from the uptake of [2,3,4,5- $^{13}\text{C}_4$]-1-deoxy-D-xylulose by *Catharanthus* cells¹¹⁴. Incorporation of [1- ^{13}C]-1-deoxy-D-xylulose into isoprenoids of the liverwort *Conocephalum conicum* could identify the involvement of MVA pathway for sesquiterpenes and MEP for diterpene, phytol⁸¹. Feeding of [5,5- $^2\text{H}_2$]-mevalonic acid lactone (MVL) and [5,5- $^2\text{H}_2$]-1-deoxy-d-xylulose (DOX) to grape leaves and berry could reveal that MEP pathway was responsible for the biosynthesis of monoterpenes¹¹⁵. Labeled precursors also helped in finding the rate of incorporation of the metabolic intermediates into pathways responsible for biosynthesis of the final metabolite¹¹⁶. Feeding experiment affords for the identification of intermediates and branching in a pathway which is evident from the [4- ^2H]-DX uptake by cells, producing two different pools of isoprene units IPP/DMAPP in 85:15 ratio, DMAPP with the retention of deuterium labeling and IPP with loss of deuterium, which showed branching in the MEP pathway, leading separately to IPP and DMAPP from the same intermediate, allylic anion of 4-hydroxy-3-methylbut-2-enyl pyrophosphate^{7, 79, 98}. These deuterium labeling have further demonstrated the fates of hydrogen atoms in

subsequent reactions in the Rohmer pathway⁶. Apart from using labeled precursor or carbon source, pulse chase experiment with ^{13}C CO₂ helped in study of plant products under normal physiological conditions¹⁸. Rapid development in the field of mass spectrometry provides the platform, not only for the accurate study of specific metabolites but the entire ^{13}C labeled metabolome of the organism¹⁹.

The contribution of MVA and MEP pathway towards isoprene production for the biosynthesis of specialized metabolites in plants has been studied extensively through stable isotopic labeling followed by its characterization using NMR^{9, 18, 56, 58, 69, 70, 72-74, 76, 77, 79, 82-84, 86, 87, 92, 104, 117-120}. NMR spectroscopy helped in identification of individual ^{13}C carbon atoms in the skeleton, which in turn will help in the retrobiosynthetic study of ^{13}C labeling positions of the intermediates and precursors contributed for its synthesis. Monoterpene moiety of alkaloid camptothecin originated from *Ophiorrhiza pimila* is synthesized through MEP pathway as predicted through *in silico* computer-aided metabolic analyses and confirmed through NMR⁷². The ^{13}C incorporation pattern not only helps in retrobiosynthetic study but also aids in understanding the isotopic randomization of C-5 (Z) and C-4 (E) methyl groups derived carbons from DMAPP⁷².

To gain insight into the isoprenoid biosynthetic pathway(s) involved in the contribution of isoprene units into limonoid skeleton, we carried out labeling experiment with [1- ^{13}C], [2- ^{13}C] glucose (Glc) isotopomers and its isotopologue, [1,6- ^{13}C] Glc in *Azadirachta indica* suspension cell cultures, which served as an experimental system for studying the biosynthesis of limonoids. We have utilized high resolution-tandem Mass spectrometry to study the limonoids produced in cell culture followed by the study of ^{13}C labeling pattern of limonoids obtained through feeding experiment. Dissection of chemical complexity of limonoids by rendition through isotopologues and isotopomers obtained with tandem MS was made possible because of high mass resolution and accuracy of MS. Isotopologues are molecules identical in chemical composition but different in isotopic composition, isotopomers (isotopic isomers) are isotopologues which differ from each other in the position of isotopic element in the molecule (Figure 3C.2A)².

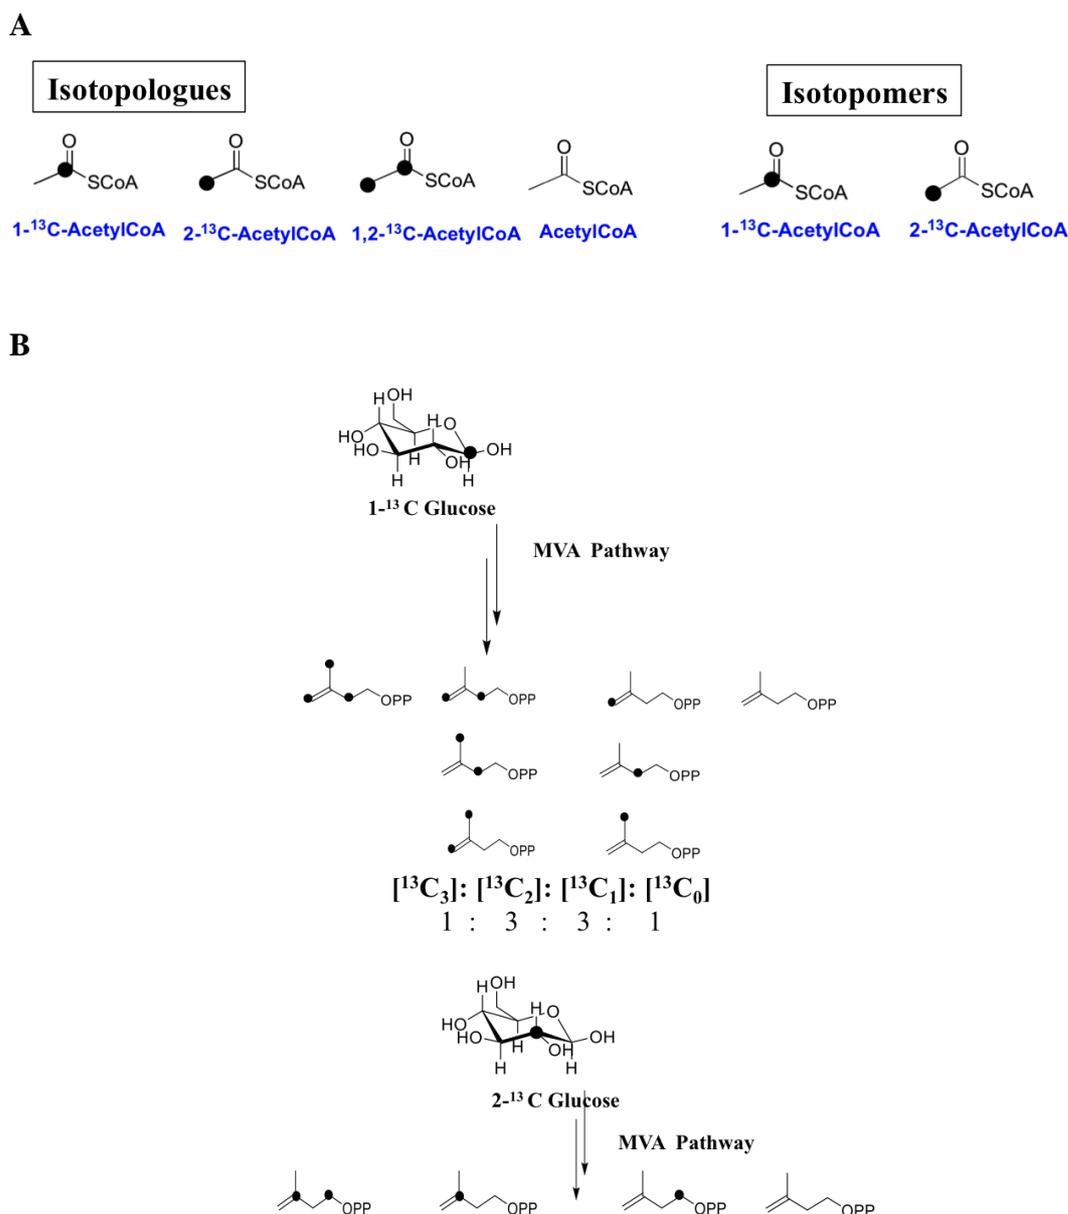

Figure 3C.2. (A) Difference between isotopologues and isotopomers represented with acetyl CoA, (B) Isotopologues and isotopomers of ¹³C labeled acetyl coA forming from [1-¹³C] Glucose and [2-¹³C] Glucose

3C.2. Results and discussion

3C.2.1. Characterization of suspension cells for limonoid biosynthesis

UPLC-ESI-MS analysis of the suspension cells derived from callus, which has been subcultured 22 times, indicated the drastic decrease in the levels of limonoids compared to the one of third stage. This was also evidenced from the [1,6-¹³C] Glc labeling study carried out with the suspension cells obtained at different subculturing

stage of callus. Limonoid isotopologues formed due to incorporation of ^{13}C label from $[1,6-^{13}\text{C}]$ Glc fed cell suspension obtained from third sub-culturing stage callus was comparatively high, however no ^{13}C incorporated limonoids detected in the cell culture derived from callus which has been sub-cultured 22 times (Figure 3C.3). Feeding experiments clearly indicated that, there is a gradual drop in the biosynthesis of limonoids in due course of subculturing of callus. Labeled limonoid were not detected in the media, these results further supports that limonoids are synthesized and stored inside the suspension cells.

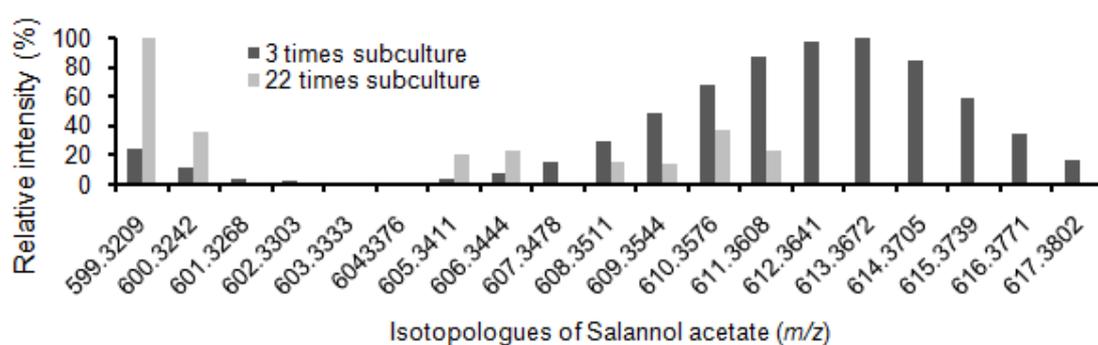

Figure 3C.3. Characterization of suspension cells for limonoid biosynthesis. Comparison of salannolacetate isotopologues formed between cell suspension obtained from callus of different subculturing stages (3 and 22) after growing the cells in the presence of D- $[1,6-^{13}\text{C}]$ Glc.

3C.2.2. Biosynthesis of limonoids: Feeding experiment with different ^{13}C labeled D-glucose tracers.

The isoprene units synthesized through MVA and MEP pathway will have different labeling patterns when cell suspension culture is fed with ^{13}C labeled D-Glucose (Figure 3C.4). This principle is taken further to investigate the contribution of isoprene units formed through MVA and MEP pathways towards the biosynthesis of limonoids, feeding experiment was carried out with different ^{13}C labeled Glucose (Glc) tracers. 24 h old neem suspension cultures were grown in liquid MS media were re-suspended in MS media containing $[1-^{13}\text{C}]$ Glc, $[2-^{13}\text{C}]$ Glc or $[1,6-^{13}\text{C}]$ Glc. The control experiment was carried out using MS media containing unlabeled glucose under similar conditions. At the end of 19 days of incubation, cell biomass were extracted for limonoids and subjected to UPLC-HRMS analysis.

Azadirachtin A, nimbin, 6-deacetylnimbin, nimbinene, 6-deacetylnimbinene, salannin, 3-deacetylsalannin, salannolacetate and nimbanal were identified in the cell

suspension generated ^{13}C isotopologues, which showed normal distribution pattern in their relative intensity. Azadirachtin A, salannin, salannolacetate, 6-deacetylnimbinene were identified in abundance with high intensity of isotopologues. The isotopologues varied in their number and intensity for each of the studied limonoid, upon labeling with different positional ^{13}C -Glc tracers. High resolution MS/MS serves as a powerful technique, and helped us for the determination of intramolecular distribution of ^{13}C in the isotopologues of the metabolite. Natural abundance of isotopologues was observed in MS for limonoids obtained from unlabeled control cell suspension (Appendix Figure 3C.5.1C, I, O, U). However, in nature, ^{13}C abundance is only 1.1% and thus the signal for lower mass fragments obtained during MS/MS spectra of limonoids are predominantly from the monoisotopic ions containing its most abundant isotope (^{12}C). However, in ^{13}C enrichment experiments, molecular ions obtained in MS are represented by different isotopologues.

UPLC-HRMS analysis of azadirachtin A obtained from the unlabeled, control cell suspension showed a protonated parent molecular ion, m/z 703.2588 ($[\text{M}-\text{H}_2\text{O}+\text{H}]^+$). Neem cell suspension enriched by feeding $[1-^{13}\text{C}]$ Glc and $[1,6-^{13}\text{C}]$ Glc yielded with 14 and 19 isotopologues, respectively (m/z 703.2588 to 717.3056 and 722.3222) (Figure 8A, Appendix Figure 3C.5.1A, B, C, D, E). $[2-^{13}\text{C}]$ Glc labeling experiment was conducted to corroborate further, the results obtained with $[1-^{13}\text{C}]$ and $[1,6-^{13}\text{C}]$ Glc. The ^{13}C enrichment of the suspension with $[2-^{13}\text{C}]$ Glc gave rise to 14 mass units to the azadirachtin A parent ion (Figure 8A, Appendix Figure 3C.2.1F). Mass spectra of 6-deacetylnimbinene from the control showed parent molecular ion $[\text{M} + \text{H}]^+$ of m/z 441.2264 (Appendix Figure 3C.5.1 G, I). Incorporation of 11 and 14 ^{13}C atoms was reflected from the comparison of unlabeled molecular ion with that of $[1-^{13}\text{C}]$ Glc and $[1,6-^{13}\text{C}]$ Glc labeling experiment, respectively (m/z 441.2264 to 452.2632 and m/z 441.2264 to 455.2730). Whereas, ^{13}C enrichment with $[2-^{13}\text{C}]$ Glc labeling culminates with 10 isotopologues (Appendix Figure 3C.5.1G, H, I, J, K, L, Figure 3C.5A). Parent molecular ion $[\text{M} + \text{H}]^+$, m/z 597.3050 was observed for salannin in the control cell culture whereas gradient increase of 14 (m/z 597.3050 to 611.3516) and 16 mass units (m/z 597.3050 to 613.3582) were generated from $[1,6-^{13}\text{C}]$ Glc as isotopic tracer. With the use of $[2-^{13}\text{C}]$ Glc as tracer, 12 isotopologues were observed (Appendix Figure 3C.5.1 M, N, O, P, Q, R, Figure 3C.6A).

Salannolacetate from the unlabeled culture generated parent ion $[\text{M}+\text{H}]^+$ of m/z

599.3209 whereas the labeled cell biomass produced 14 and 18 isotopologues upon [1-¹³C] and [1,6-¹³C] Glc labeling, respectively (m/z 599.3209 to 613.3672 and 617.3802 respectively). In case of [2-¹³C] Glc labeling, isotopologues with 13 mass units were observed in addition to the parent ion (m/z 599.3209 to 612.3672) (Figure 3C.7A, Appendix Figure 3C.5.1S, T, U, V, W, X). In order to dissect the position of ¹³C in the above limonoid skeletons, tandem MS fragmentation of the limonoid obtained from the labeled and unlabeled culture need to be compared. Structure-fragment relationship for C-seco limonoids such as salannin, salannolacetate and 6-deacetylnimbinene has been established in our previous study. However, there is no report on ESI based tandem mass spectrometric characterization of azadirachtin. Herein, we report structure-fragment relationships for azadirachtin using UPLC-ESI-quadrupole/orbitrap-MS. These data will be utilized for tracing their biosynthetic pathway for these limonoids in neem suspension culture fed with [1-¹³C] Glc, [2-¹³C] Glc or [1,6-¹³C] Glc.

3C.2.3. Tracing the limonoid biosynthesis through neem cell suspension feeding experiments

After understanding the fragmentation pattern for azadirachtin A, we subjected its isotopologues obtained through incorporation of ¹³C labels from [1-¹³C], [1,6-¹³C] and [2-¹³C] Glc feeding experiments, in order to identify the position of each ¹³C label in the skeleton of limonoids. MS/MS traces obtained with NCE of 20% for each of the limonoid isotopologue were compared with that of unlabeled fragments to establish the number of ¹³C labels present in that fragment (Figure. 3C.5, Figure. 3C.6, Figure. 3C.7, Figure. 3C.8, Appendix Figure. 3C.5.2). The ¹³C-enriched fragmentation pattern thus obtained was further subjected to retro-biosynthetic label tracing approach by applying to squalene intermediated model of triterpene origami for azadirachtin biosynthesis, to probe the origin of each carbon through MVA or/and MEP pathways. According to the biosynthetic pathway of triterpene origami, tetranor- and pentanor-limonoids are formed through loss of four and five isoprenogenic carbons from the C₃₀ triterpene skeleton and gain of further non-isoprenogenic carbon as functional groups.

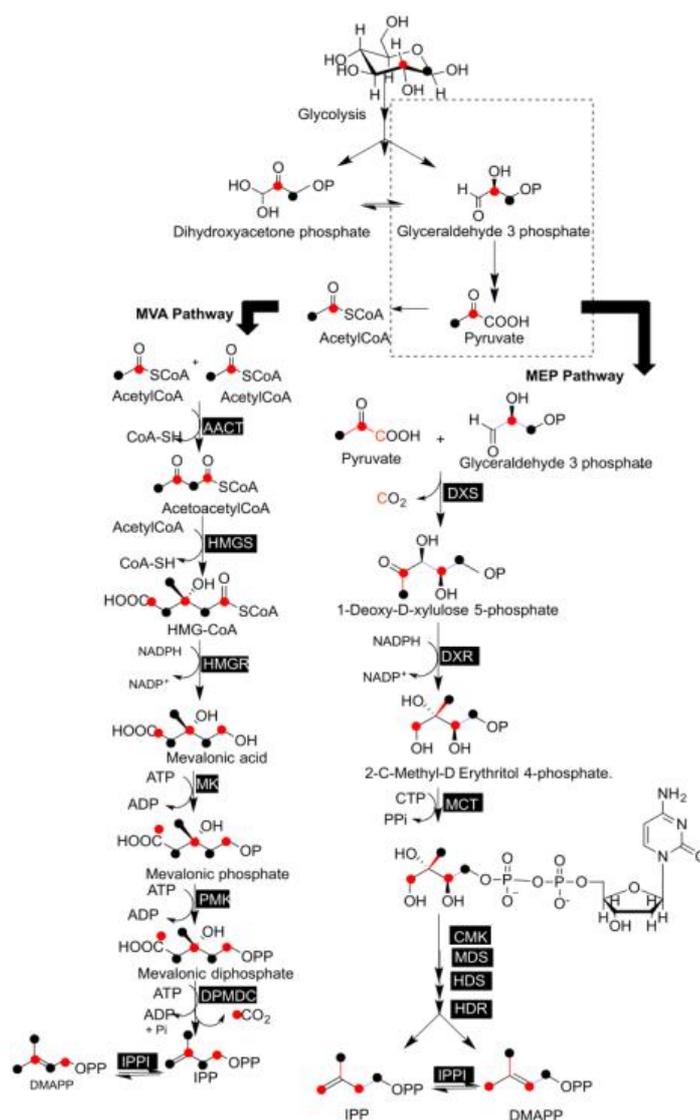

Figure 3C.4. Tracing the flow of ^{13}C from glucose through MVA and MEP pathway for the biosynthesis of isoprene unit. The black dot represents the ^{13}C carbon derived from 1- ^{13}C label /1,6 - ^{13}C of D-glucose and the red one from 2- ^{13}C label of D-glucose. AACT, acetoacetyl-CoA thiolase; HMGS, 3-hydroxy-3 methyl glutaryl coenzyme A synthase; HMGR, 3-hydroxy-3-methyl glutaryl coenzyme A reductase; MK, mevalonate kinase; PMK, 5-phosphomevalonate kinase; DPMDC, diphosphomevalonate decarboxylase; IPPI, isopentenyl diphosphate isomerase; DXS, 1-deoxy-D-xylulose-5-phosphate synthase; DXR, 1-deoxy-D-xylulose-5-phosphate reductoisomerase; MCT, 2-C-methyl-D-erythritol-4 phosphate cytidyltransferase; CMK, 4-(Cytidine 5'-diphospho)-2-C-methyl-D-erythritol kinase; MDS, 2-C-methyl-D-erythritol 2,4-cyclodiphosphate synthase; HDS, 4-hydroxy-3-methylbut-2-enyl diphosphate synthase; HDR, 4-hydroxy-3-methylbut-2-enyl diphosphate reductase.

It is well established in literature^{15, 47}, that labeling with [1- ^{13}C] Glc culminates with IPP or DMAPP labeled at C-2, C-4, C-5 when they are formed through MVA pathway whereas ^{13}C will be incorporated into isoprene units at C-1 and C-5 in case of

their biosynthesis through MEP route (Figure 3C.4). In case of [1,6-¹³C] Glc labeling, two 2-¹³C acetyl-CoA are generated from a Glc molecule unlike that of one unlabeled and one 2-¹³C acetyl-CoA formed through [1-¹³C] Glc as tracer (Figure 3C.2B). Metabolism of acetyl-CoA formed from [2-¹³C] Glc result in labeling of isoprene units at C-1 and C-3 through MVA pathway, whereas at C-2 and C-4 in case of MEP pathway (Figure. 3C.4). Based on the above information on labeling pattern of isoprene, and considering the number of incorporated ¹³C carbons on each of the fragments from tandem MS analysis, the pattern was fitted into the above origami model. Isotopologues generated for each of the signature fragment of labeled limonoids such as 6-deacetylnimbinene, salannin, salannolacetate and azadirachtin A are discussed in detail.

The fragment, *m/z* 147.0804 possess characteristic signature of C-seco limonoids such as salannolacetate, salannin, 3-deacetylsalannin, nimbin, 6-deacetylnimbin, nimbinene, 6-deacetylnimbinene and nimbanal corresponding to the C- and D-ring with 17-furan moiety, as per our earlier study⁴⁵. This fragment encompasses two isoprene units and 1 carbon from third isoprene. Feeding experiment with [1-¹³C]/ [1,6-¹³C] Glc resulted in six isotopologues, possibly through three ¹³C in each of the two isoprenes thereby, ignoring the participation of MEP, as only two carbons of isoprene get labeled via latter pathway. Whereas [2-¹³C] Glc experiment did not provide any useful insight into tracing the pathway as two ¹³C labeled isoprenes can be obtained through both pathways however at different positions resulting in increase in 4 mass units to the fragment.

Amongst the nine limonoids identified in the culture, nimbinene and 6-deacetylnimbinene constitute the class of penta-nortriterpenoids. It is important to note that the maximum number of ¹³C incorporated into 6-deacetylnimbinene skeleton are 14 through [1,6-¹³C] Glc labeling, corroborating to the fact that three ¹³C may be lost during the excision of the terminal four carbons in the formation of proto-limonoid and another carbon from A ring during the formation of penta-nortriterpenoids (Figure 3C.5). The signature fragment, *m/z* 187.1119 corresponding to the decalin moiety was identified exclusively in this class of limonoids and this decalin moiety are constituted from first 3 isoprene units of squalene epoxide. Comparison of control and labeled culture, revealed the formation of 8 isotopologues in [1-¹³C] Glc labeling. If, it had been formed through MEP route, only five ¹³C labels would be incorporated into it. In case of [2-¹³C] Glc labeling, five mass units were observed however, labeling through either of the

pathways may result in same number of labels into this fragment. Further, the fragment of m/z 409.2010, obtained after the removal of MeOH from the methylester group from the parent ion represents 6-deacetylnimbinene skeleton, composed of 4 complete isoprene units and 2 incomplete units which has lost its carbons from the triterpene skeleton, during the process of its biogenesis. It gave away fourteen isotopologues in [1- ^{13}C] Glc labeling experiment and eleven in [2- ^{13}C] Glc labeling, providing us with the evidence that isoprene units are derived from MVA route and also the methylgroup is of non-isoprenogenic origin (Figure 3C.5, Appendix Figure 3C.5.1)¹²¹.

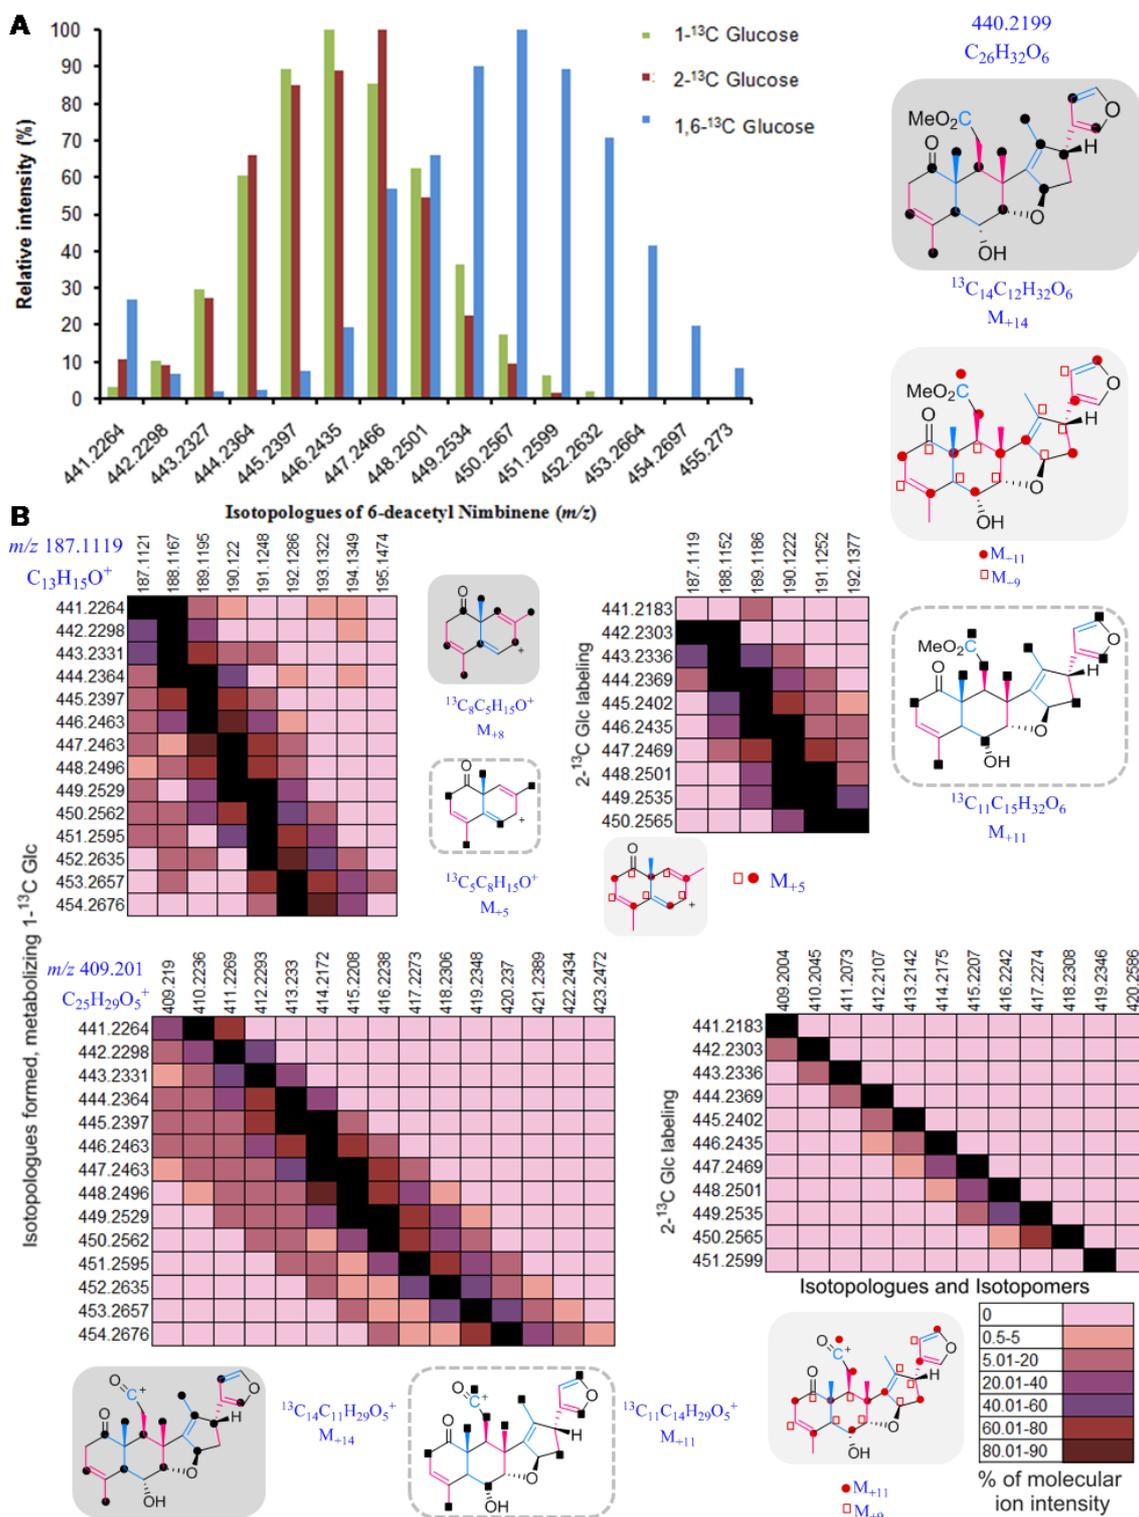

Figure 3C.5. Comparison of relative intensity of isotopologues obtained with the uptake of different ^{13}C -glucose tracers. (a) MS of 6-deacetylnimbinene isotopologues (b) Heatmap for distribution of isotopologues for specific fragments (m/z 187.1119, 409.2010 contributing to different part of skeleton respectively) for each 6-deacetylnimbinene isotopologues obtained from $[1-^{13}C]$ Glc (left) and $[2-^{13}C]$ Glc (right) labeling experiments. (M represents the m/z of parent ion of the molecular ion/ fragment)

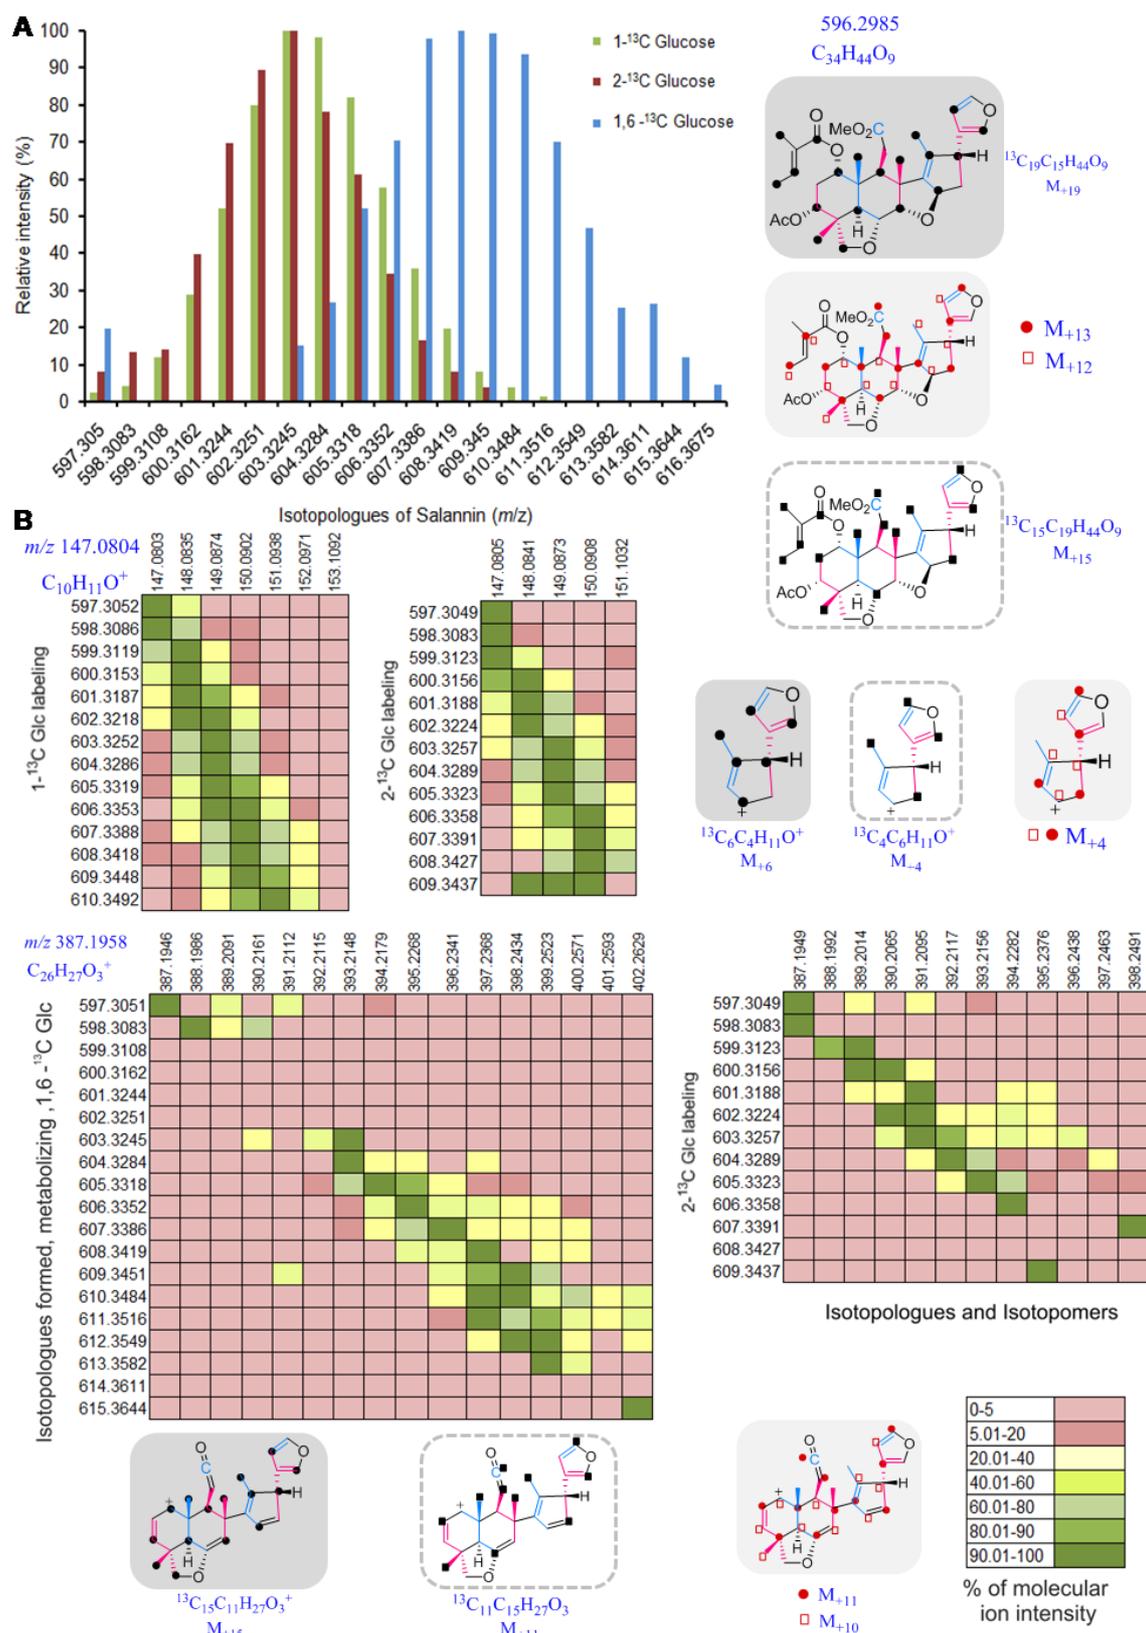

Figure 3C.6. Relative intensity of salannin isotopologues obtained from labeling study with different tracers such as [1-¹³C], [2-¹³C], [1,6-¹³C] Glc. (a) MS of salannin isotopologues formed from three different Glc tracers (b) MS/MS distribution of isotopologues of the fragments

(shown here are m/z 147.0804 and 387.1946 representing the skeleton). (M represents the m/z of parent ion of the molecular ion/ fragment) (heatmap at left corresponds to isotopologues formed through $[1-^{13}\text{C}]$ / $[1,6-^{13}\text{C}]$ Glc labeling and for the $[2-^{13}\text{C}]$ Glc labeling at the right).

One of the signature fragment of salannin is m/z 387.1958, corresponding to its triterpene skeleton, which is without 3 functional groups *viz.*, MeOH, tiglic acid and acetic acid (Appendix Figure 3C.5.2, Figure 3C.6). Similarly, the fragment, m/z 419.2214, of salannolacetate gave the same skeleton but with intact methylester moiety (only devoid of isovalerate and acetate group) (Figure 3C.7, Appendix Figure 3C.5.2). These skeletal fragments comprises of 5 complete isoprene units and an incomplete isoprene unit (with only one carbon contribution from it). These fragments have been originated from 26 isoprenogenic carbons and in addition, 1 non-isoprenogenic carbon at methylester group in case of m/z 419.2214. $[1,6-^{13}\text{C}]$ Glc labeling showed addition of 15 mass units for these fragments, which might have arrived from 5 isoprenes each with three ^{13}C labels, indicating that they may have originated through MVA pathway. Eleven ^{13}C incorporations occurring in $[2-^{13}\text{C}]$ Glc labeling further provides the evidence that isoprene units are formed through MVA as the alternative route will result in only 10 labels due to loss of one during the formation of proto-limonoids (Figure 3C.6B, Appendix Figure 3C.5.2).

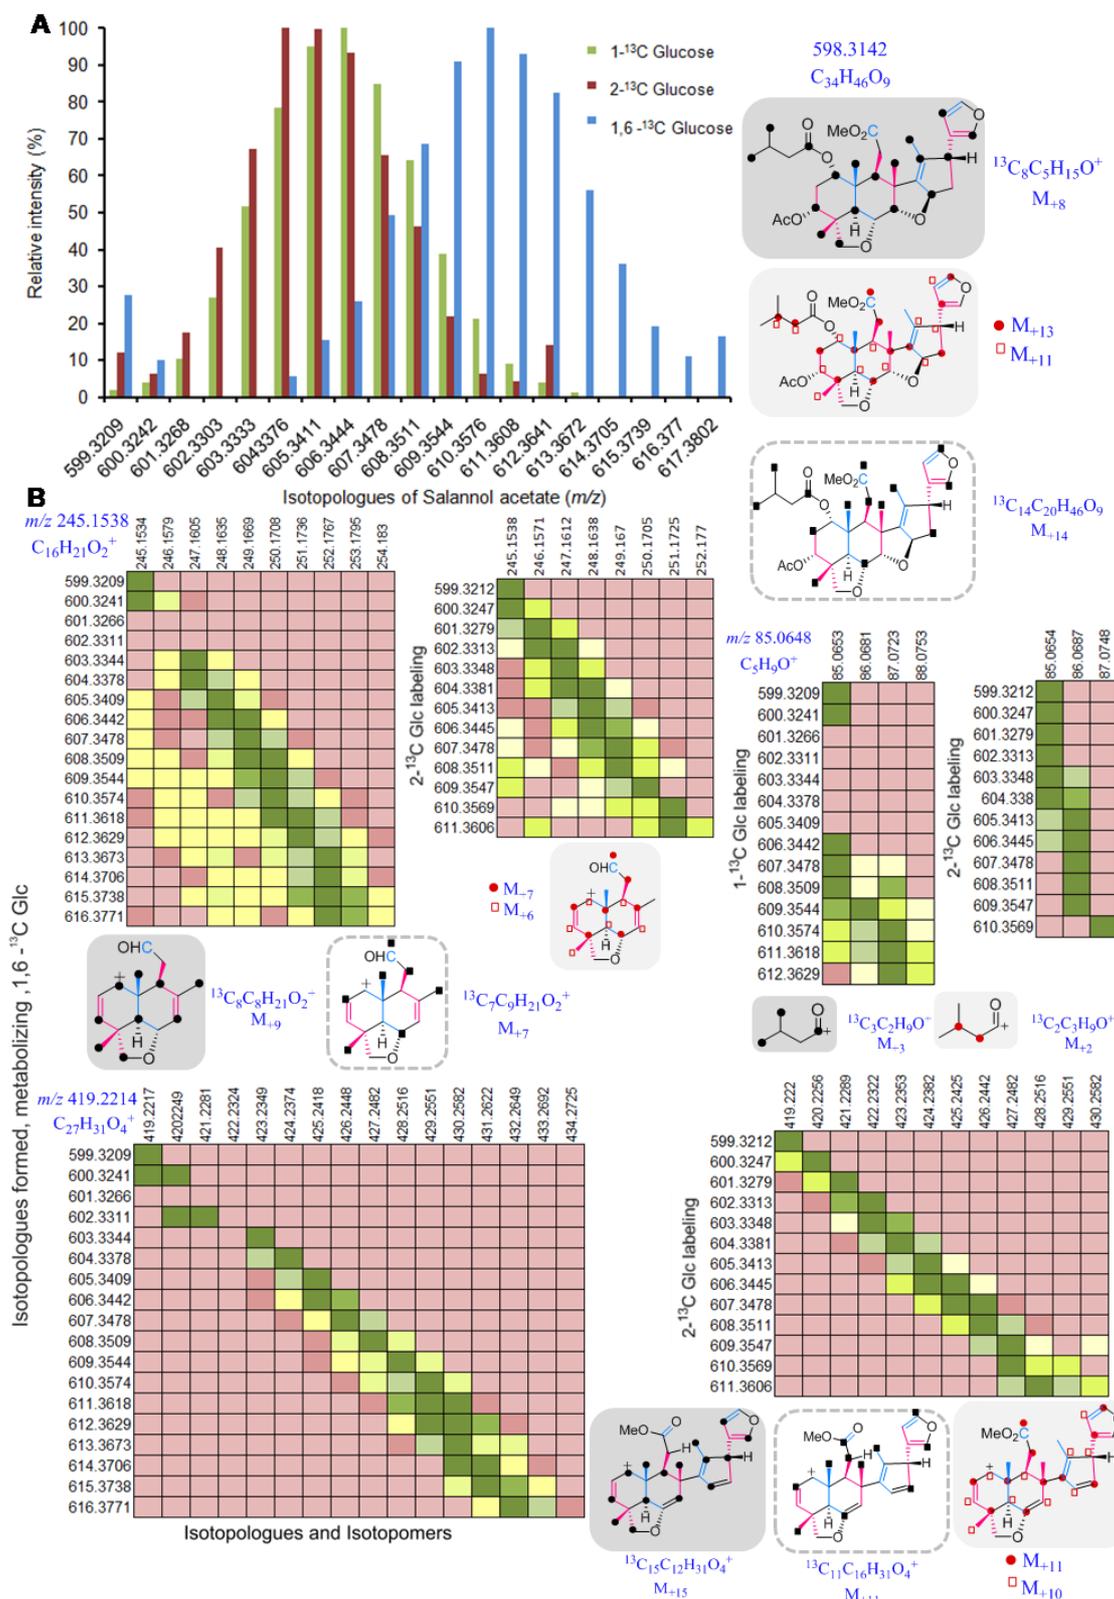

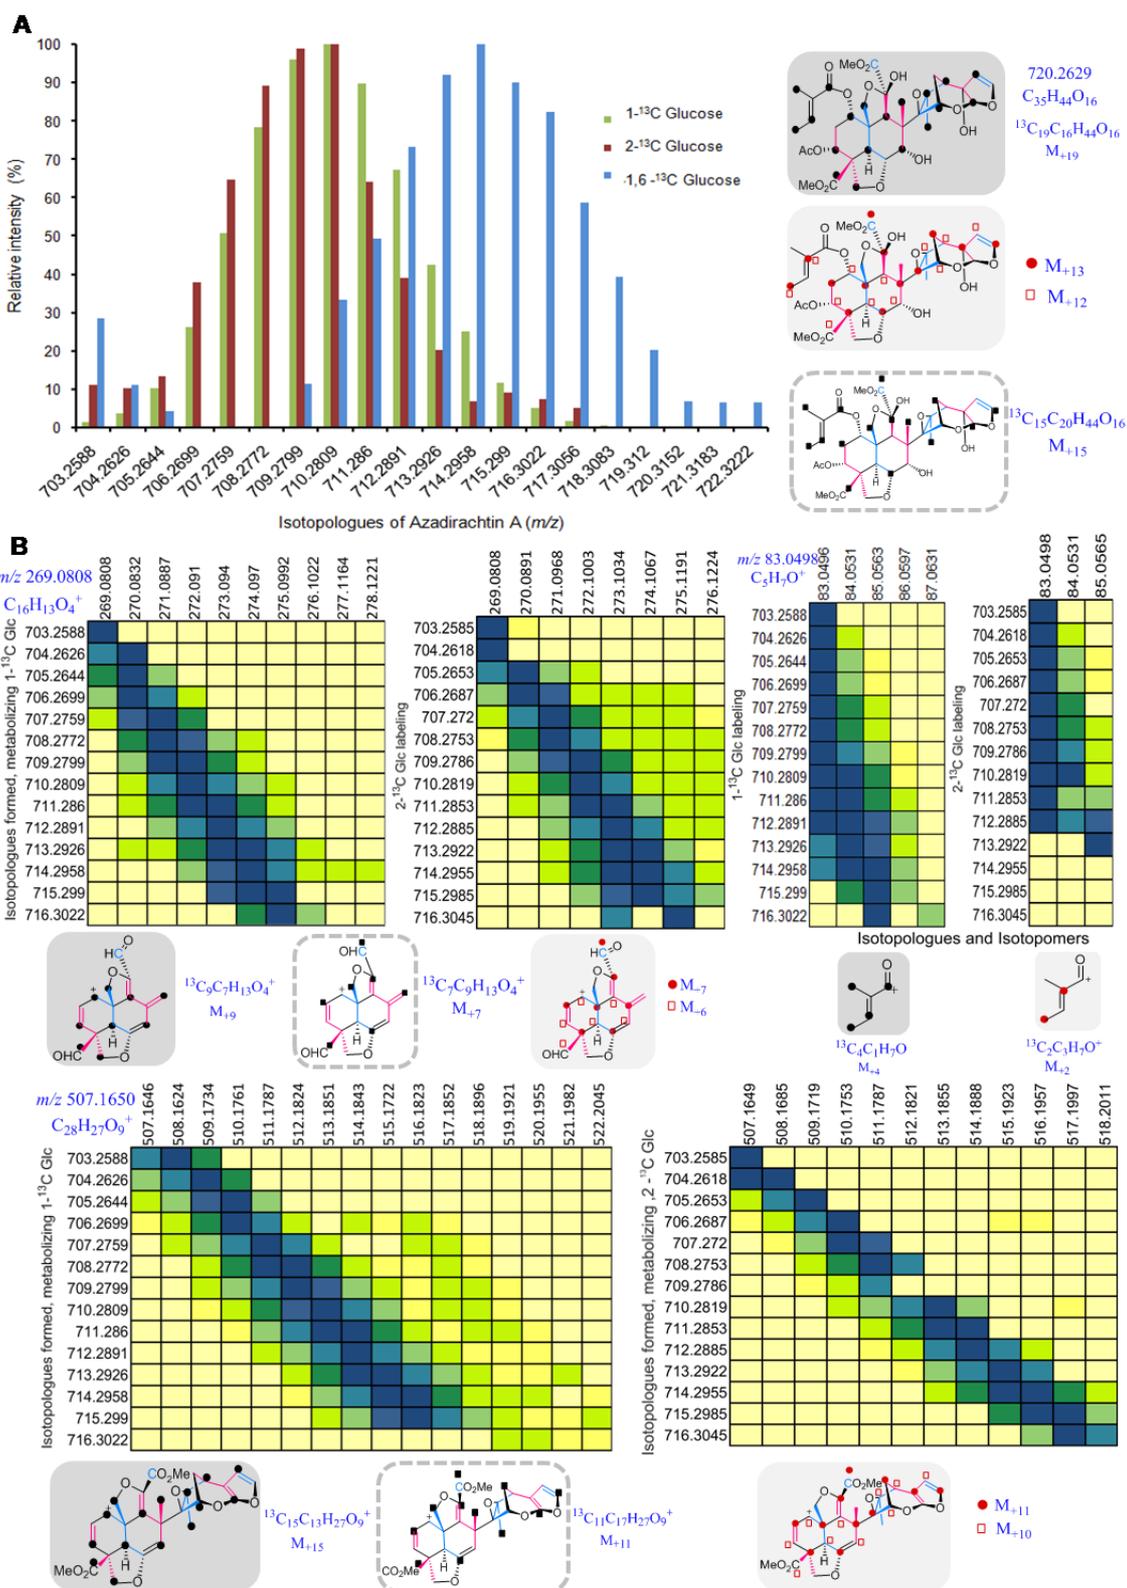

Figure 3C.7. Relative intensity of salannolacetate isotopologues formed through labeling study with different tracers of Glucose ([1-¹³C], [2-¹³C] and [1,6-¹³C]) and the number of ¹³C carbon incorporation evident from tandem MS analysis of the isotopologues. (a) MS of salannolacetate isotopologues formed through different ¹³C Gic feeding experiments (b) MS/MS

distribution of isotopologues of the fragments (m/z 85.0648, 245.1538, 419.2214). Heatmap at the left corresponding to isotopologues formed through either $[1-^{13}\text{C}]$ or $[1,6-^{13}\text{C}]$ Glucose and the one at the right correspond to isotopologues formed through $[2-^{13}\text{C}]$ Glc. (M represents the m/z of parent ion of the molecular ion/ fragment).

Further evidence was obtained after studying salannolacetate, for its fragment, m/z 245.1538 corresponding to decalin moiety, which is devoid of CH_2O group at methylester moiety and other functional groups. This fragment is built from 3 complete isoprene units and 1 carbon of fourth isoprene. $[1,6-^{13}\text{C}]$ and $[2-^{13}\text{C}]$ Glc labeling study arrived, with addition of 9 and 7 mass units for this fragment respectively, (Figure 3C.7B), thus corroborating its formation through MVA route. The same pattern of increase in mass units was obtained for another decalin fragment m/z 273.1414 (with intact methylester moiety) corresponding to salannin and salannolacetate (Appendix Figure 3C.5.1). MS/MS traces of unlabeled salannolacetate generated daughter ion, m/z 85.0653 corresponding to isovalerate moiety and the ones of labeled salannolacetate showed an increase of 3 mass units (m/z 86.0681, 87.0723, 88.0753) (Figure 3C.7B). Isovalerate biosynthesis was traced through primary metabolism leading to amino acid biosynthesis as it diverges from leucine biosynthesis, which corroborates with the formation of 3 mass units in our labeling experiment. Isovalerate was traced through glycolysis and amino acid leucine biosynthetic pathway, which is in agreement with previous study in *Propionibacterium*¹²². Two molecules of $[3-^{13}\text{C}]$ pyruvate and one $[2-^{13}\text{C}]$ acetyl-CoA formed from the glycolysis of $[1,6-^{13}\text{C}]$ Glc contribute for the biosynthesis of leucine (Figure 3C.9B). Isovalerate originates from ketoisocaproate, a penultimate metabolite in leucine biosynthetic pathway thereby acquiring two ^{13}C from labeled pyruvate and one from acetyl-CoA. Our tandem MS data for the isotopologues of salannolacetate supports the presence of three ^{13}C labels in isovalerate as evidenced from 3 additional units generated from the fragmentation of salannolacetate isotopologues (Figure 3C.7B).

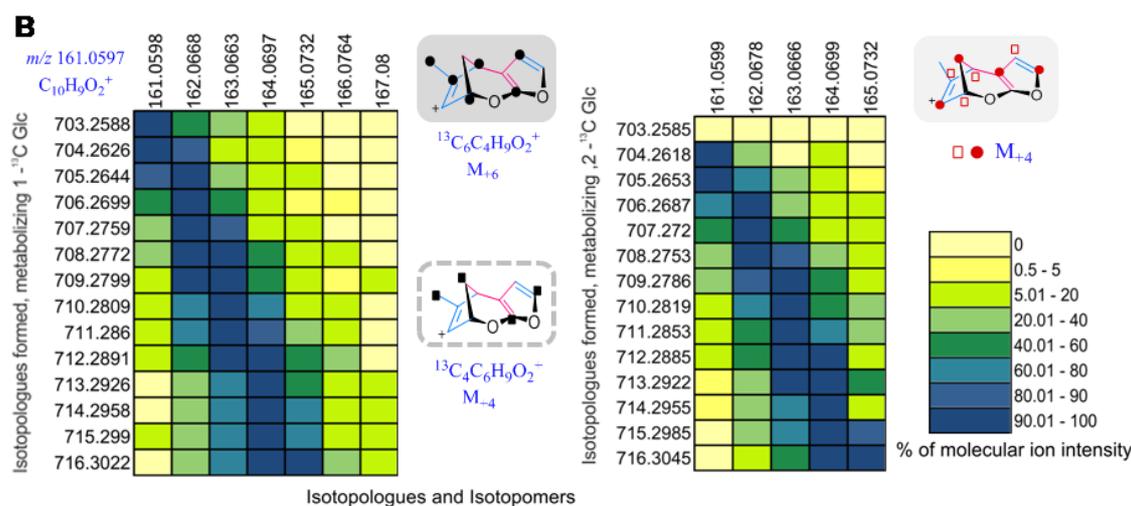

Figure 3C.8. Distribution of azadirachtin A isotopologues and isotopomers obtained from ESI-MS and MS/MS analysis. (a) Comparison of relative intensity of isotopologues of protonated ion adduct $[M-H_2O+H]^+$ of azadirachtin A obtained from independent labeling experiments with $[1-^{13}C]$, $[2-^{13}C]$, $[1,6-^{13}C]$ Glc. (b) Heatmap of isotopologue of azadirachtin A in the mass spectra vs. relative intensity of each of the isotopologues for individual fragments (m/z 83.0498, 161.0597, 269.0808, 507.1650 derived from different part of the skeleton are represented) obtained when subjected to tandem MS at collision energy of 20%. The structure of the molecule and its fragments are given in grey boxes for the molecule denoting its ^{13}C pattern of formation through MVA pathway and dashed line boxes for its formation through MEP pathway. The black dots and squares represent the position of ^{13}C carbon incorporated from $[1-^{13}C]$ Glc / $[1,6-^{13}C]$ Glc whereas the red dots corresponding to those from $[2-^{13}C]$ Glc.

When we examined the fragmentation pattern of azadirachtin A obtained from the unlabeled biomass, m/z 269.0808 was corresponding to the decalin moiety. Three isoprene units and a single carbon from fourth isoprene contribute to this moiety. ^{13}C enrichment through $[1-^{13}C]$ Glc labeling showed additional 9 mass units to this fragment suggesting that each of the three ^{13}C labels may have originated from a single isoprene unit. The same experiment with $[2-^{13}C]$ Glc labeling gave 7 additional mass units further corroborating its route of origin (Figure 3C.8B). The fragment m/z 507.1650 of azadirachtin A was formed devoid of all functional groups except the methylester moieties and this fragment encompasses 5 isoprenes and single carbon of terminal isoprene. This fragment showed additional 15 mass units upon $[1-^{13}C]$ Glc labeling and generated 11 mass units upon $[2-^{13}C]$ Glc labeling (Figure 3C.8B). The fragment m/z 161.0597 formed from the C, D rings and furan moiety of azadirachtin A, is originated from three isoprene units. This fragment displayed six and four additional mass units corresponding to the $[1-^{13}C]$ Glc and $[2-^{13}C]$ Glc labeling experiment respectively,

indicating that it is biosynthesized by utilizing IPP and DMAPP formed through MVA pathway (Figure. 3C.8B, Figure. 3C.5.2).

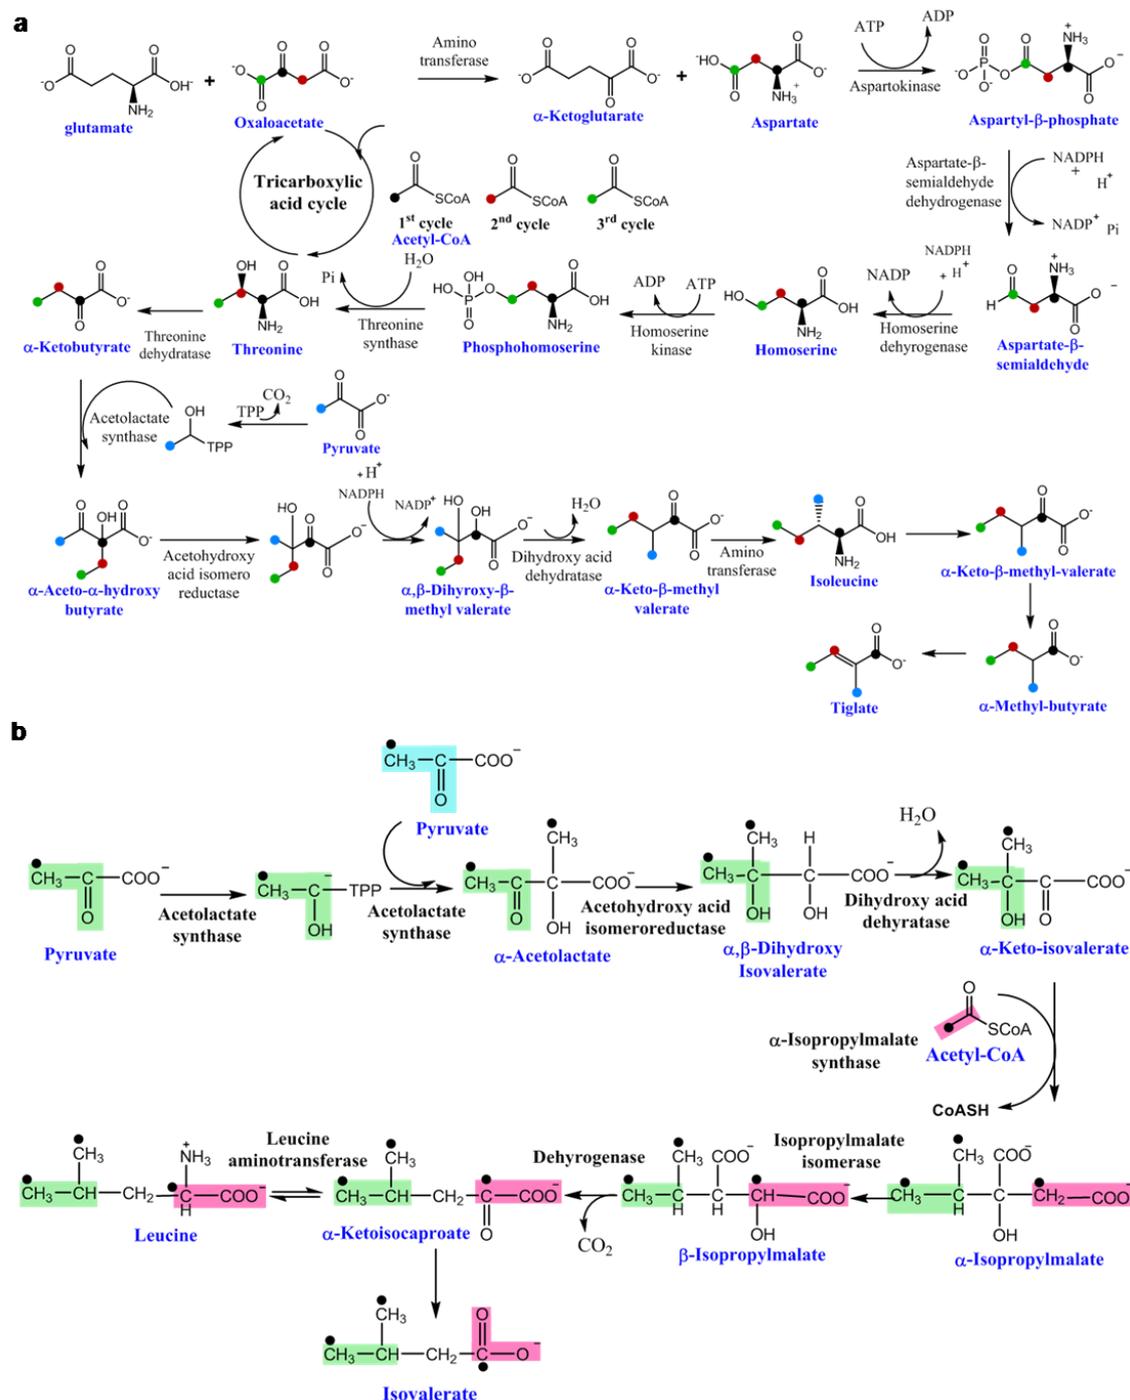

Figure 3C.9. Tracing the flow of ^{13}C carbon from $[1-^{13}\text{C}]$ / $[1,6-^{13}\text{C}]$ Glc through primary metabolic pathway for the formation of functional groups present in limonoids. (a) tiglata group present in azadirachtin and salannin is traced through isoleucine biosynthetic pathways. (b) isovalerate group present in salannolactate is traced through leucine biosynthetic pathway.

The daughter ion fragment, m/z 83.0498, was identified as tiglate group from azadirachtin A, salannin and 3-deacetylsalannin. Four additional mass units (m/z 84.0531, 85.0565, 86.0597, 87.0718) were generated after fragmentation of labeled azadirachtin A from $[1-^{13}\text{C}]$ / $[1,6-^{13}\text{C}]$ Glc labeling whereas two mass units increase were observed through $[2-^{13}\text{C}]$ Glc labeling experiment. The earlier report supports the formation of tiglic acid through isoleucine biosynthetic pathway, so its origami was traced through multiple primary metabolic pathways (Figure 3C.9). A plausible scheme (Figure 3C.9) is presented to determine the carbon position specific biosynthetic origin of tiglate moiety present in azadirachtin A. The $[2-^{13}\text{C}]$ acetyl-CoA entering the TCA cycle derives its ^{13}C label from the C-1 and C-6 positions of $[1,6-^{13}\text{C}]$ Glc thereby labeling oxaloacetate, the TCA intermediate in subsequent cycles. The resulting oxaloacetate gets ^{13}C label at three carbons producing aspartate labeled at C-2, C-3 and C-4 positions which in turn is utilized in threonine biosynthetic pathway, labeling the same positions of carbon in threonine. The amino acid, threonine by addition of another ^{13}C label from $[3-^{13}\text{C}]$ pyruvate followed by isomerization, reduction, dehydration and group transfer reactions forms isoleucine. Isoleucine is converted in two-step reactions to tiglate containing four ^{13}C labels. This is corroborated from the four additional mass units generated from MS/MS fragmentation of isotopologues of azadirachtin and salannin (Figure 3C.8, 3C.9).

The elaborated pattern of ^{13}C distribution in the limonoid skeleton and its functional group obtained through tandem MS analysis of the *ex vivo* biosynthesized metabolite gives us the evidence that MVA pathway contributes for the biosynthesis of limonoids and the functional groups such as tiglate and isovalerate are formed through isoleucine and leucine amino acid biosynthetic pathways (Figure 3C.5, 3C.6, 3C.7, 3C.8, 3C.9, 3C.10, Appendix Figure 3C.5.1, Appendix Figure 3C.5.2).

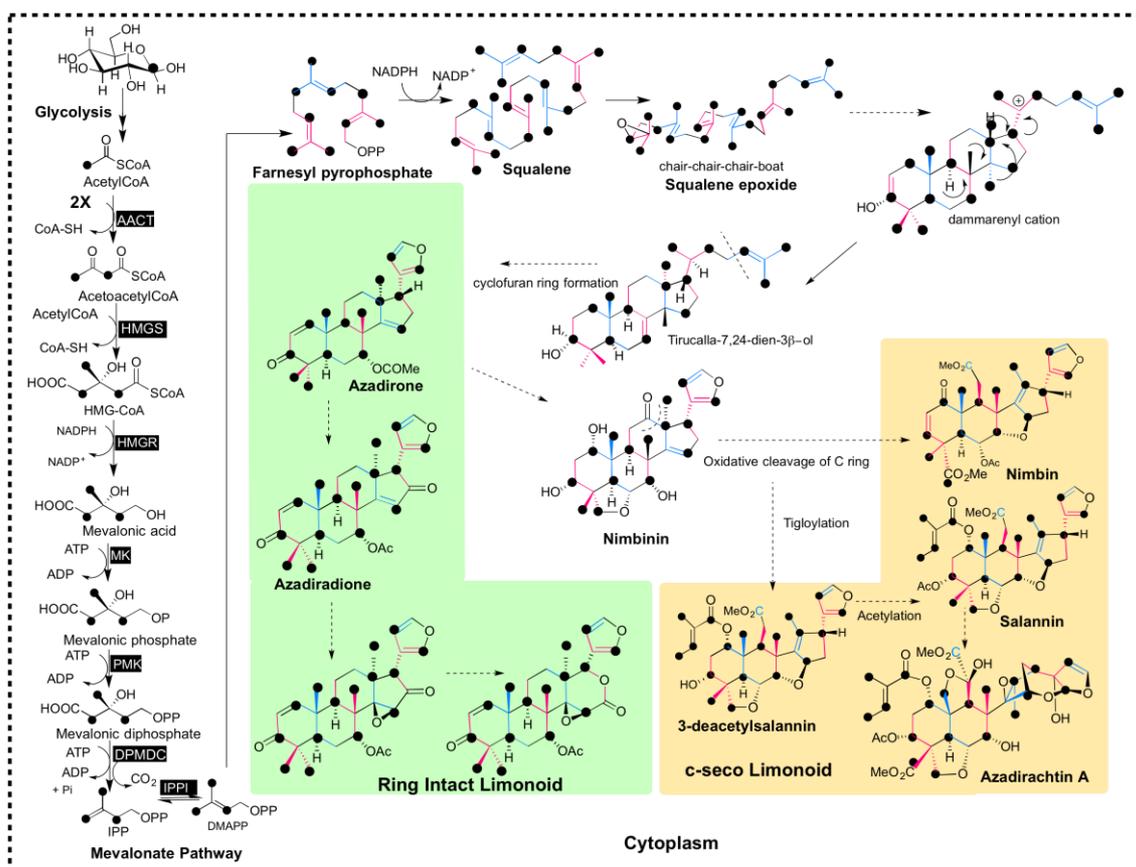

Figure 3C.10. Simplified scheme showing limonoid biosynthesis in neem being contributed by isoprene units formed through MVA pathways evident from the labeling experiment with ^{13}C glucose. C-seco and ring intact limonoid are represented in yellow and green boxes respectively. (Alternate isoprene units of the limonoid skeleton are shown in pink and blue, dotted arrow shown here are the uncharacterized steps in the pathway).

3C.3. Conclusion

Study of limonoid biosynthesis in neem tree is of potential significance as it produces agriculturally and pharmacologically important molecules. Limonoid biosynthesis of neem tree and cell lines have been unraveled through comparative quantification of limonoids with that of neem tree and through ^{13}C limonoid isotopologues analysis. Furthermore, mevalonate pathway exclusively contributes for isoprene units of limonoids as evidenced through stable isotope labeling. The work emphasizes the crucial role of MVA pathway and found to be the sole source of isoprene units for limonoid biosynthesis.

3C.4. Materials and methods

3C.4.1. Feeding Experiment with ^{13}C Glc tracers

For feeding experiments, cells from 2 days old suspension was harvested from media and sub-cultured into media with labeled carbon source. Feeding experiments with D-[1-¹³C] Glc, D-[2-¹³C] Glc and D-[1,6-¹³C] Glc (99% enriched, Cambridge Isotope Lab. Inc., Andover, MA) were performed separately in 25 mL Erlenmeyer flasks containing 5 mL MS liquid with 3% of labeled Glucose in duplicates.

3C.4.2. Harvesting cells and Extraction of limonoids

The suspension culture cells were collected from media by centrifugation at 2500 × *g* for 10 min at 25 °C. The cells were homogenized in ice-cold methanol. The supernatant was collected after centrifugation at 2500 × *g* for 10 min at 25 °C. The cells were again resuspended in twice the volume of methanol and extracted twice again. The methanol extract was pooled together and evaporated to dryness. The residue was partitioned between water and ethylacetate thrice. The ethylacetate pool was then evaporated to dryness under reduced pressure and constituted with LC-MS grade methanol to the volume of 1 mL. To quantify limonoids in the media, it was partitioned with ethylacetate and extracted, as mentioned above.

3C.4.3. LC-ESI-Mass Spectrometry conditions

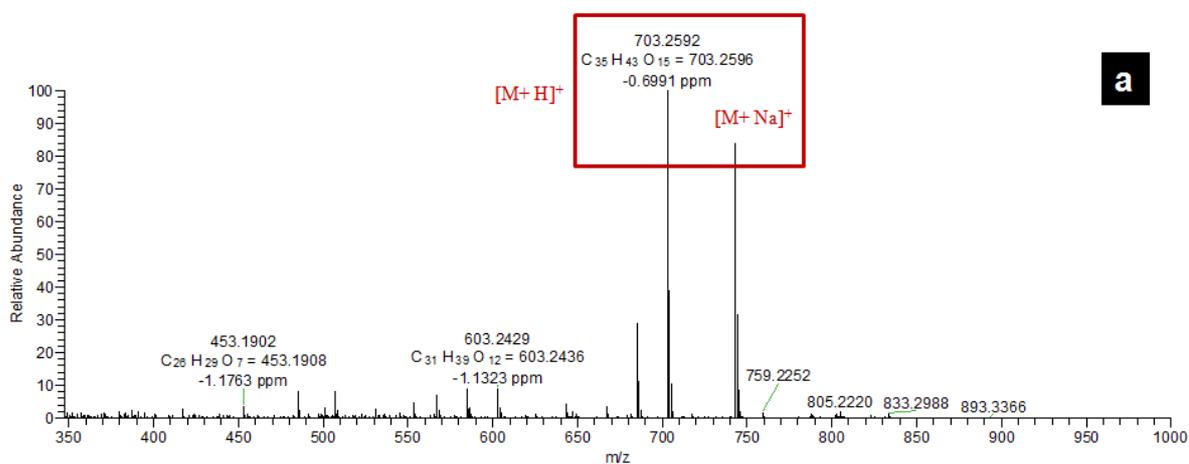

Analysis of neem limonoids was performed with Thermo Scientific QExactive™ hybrid quadrupole-Orbitrap mass spectrometer associated with Accela 1250 pump and Accela open AS. The conditions of HESI source include capillary temperature of 320 °C, Heater temperature at 350 °C, s-lens RF level of 50, Spray voltage of 3.6 kV, spray current of 0.9 μA with sheath gas flow rate of 41, Auxiliary gas flow rate of 9 and sweep gas flow rate of 3. Standards as well as the extracted samples were analyzed in positive ionization mode, in full MS-scan with scan range of 100 to 1000 *m/z*. Following were the properties of the scan performed- resolution 70,000, AGC target 1e6, Maximum IT 200 ms. Waters Acquity UPLC BEH C₁₈ column (particle size 1.7 μm, 2.1 X 100 mm) was used as the stationary phase while the solvent system of methanol and water containing 0.1% formic acid served as the mobile phase. The gradient started with 40% methanol (5 min isocratic), it was then increased to 50% (5 min isocratic), followed by 60% methanol for the next 15 minutes and over the next 4 minutes it was isocratic with 65% methanol. It was then increased to 90% methanol for 4 minutes. For the last 2 minutes, it was isocratic with 40% methanol. Constant flow rate of 0.3 mL min⁻¹ was

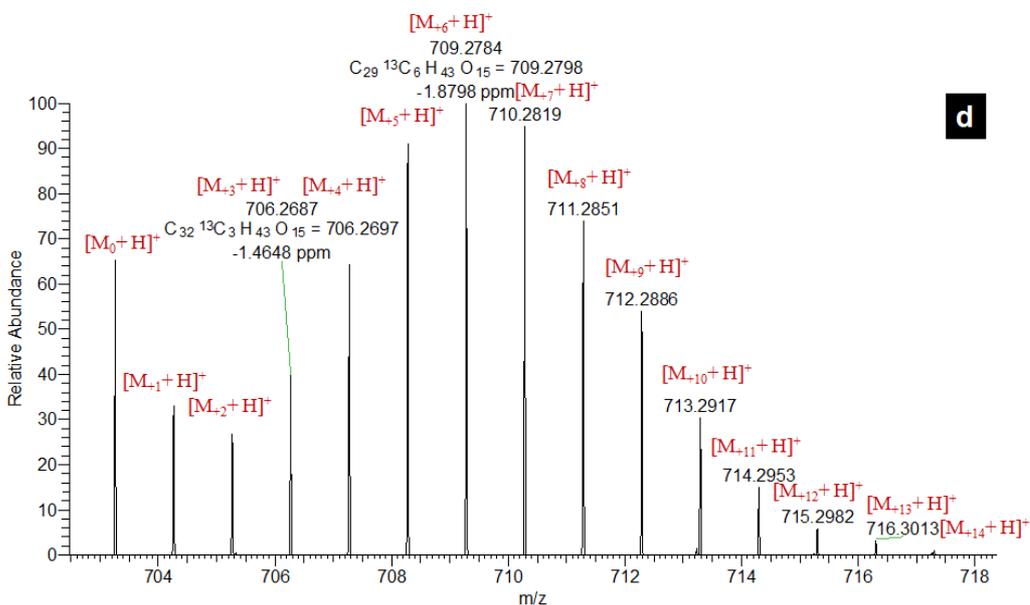

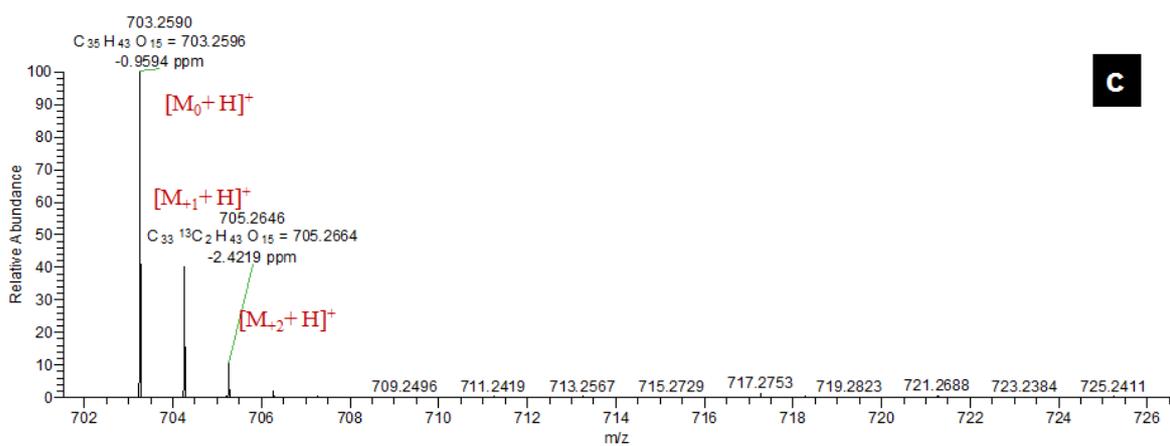

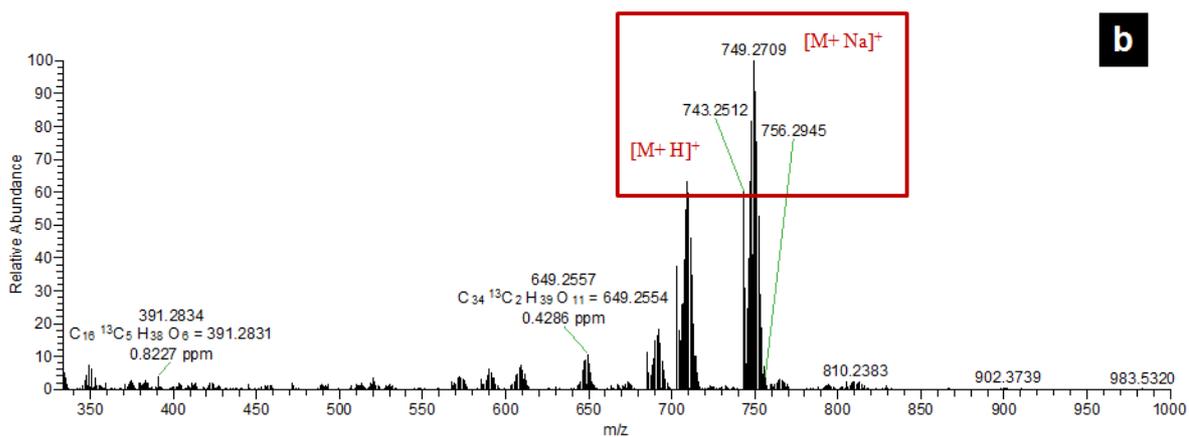

maintained throughout the run time of 35 min. The chromatograms and mass spectral data were processed by Xcaliburqual browser (version 2.3; Thermo Scientific).

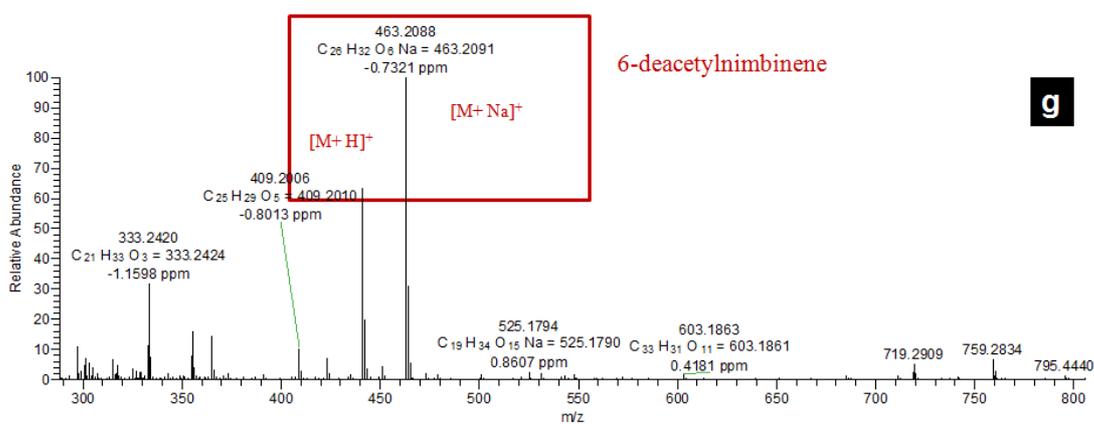

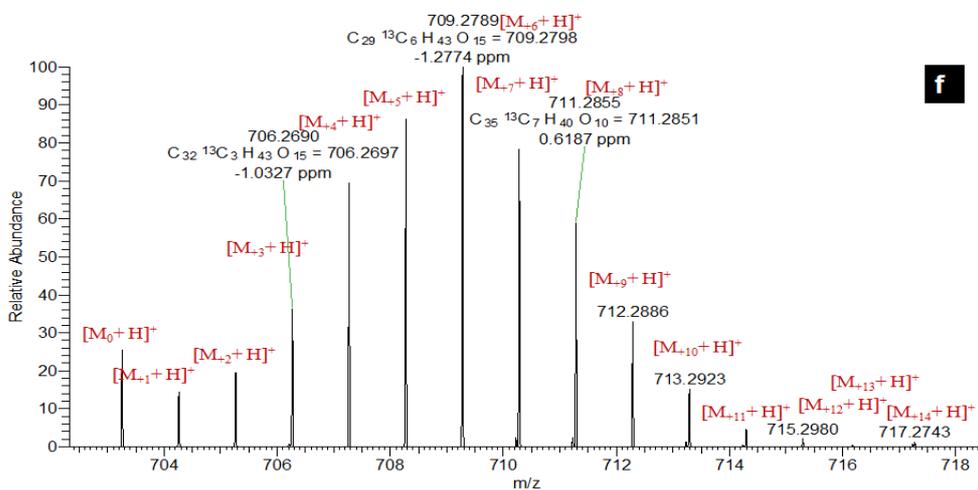

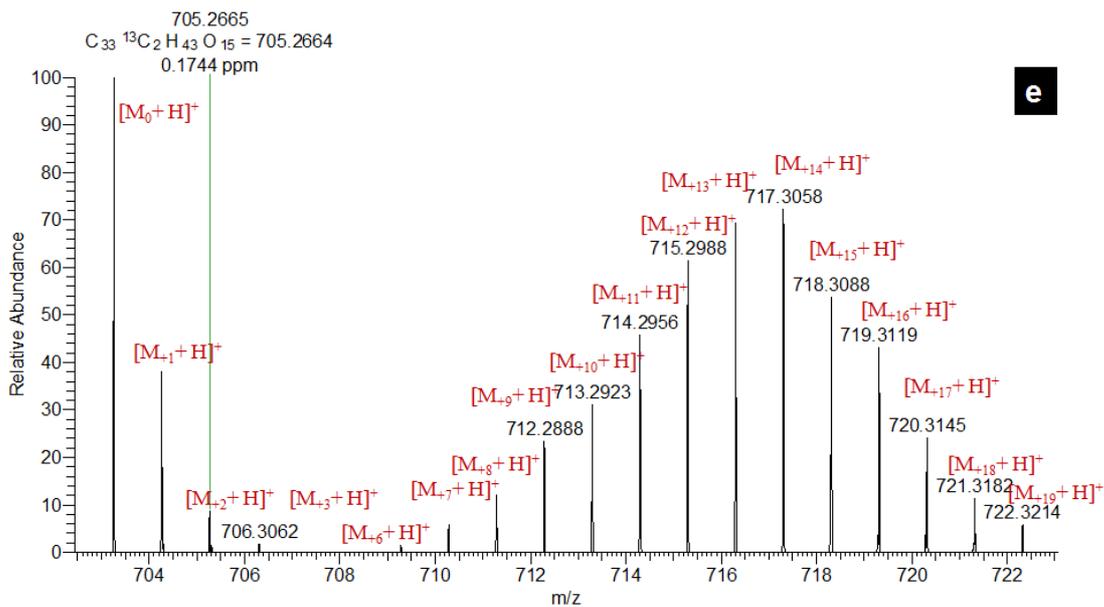

3C.4.4. Tandem Mass Spectrometry of limonoids and its isotopologues

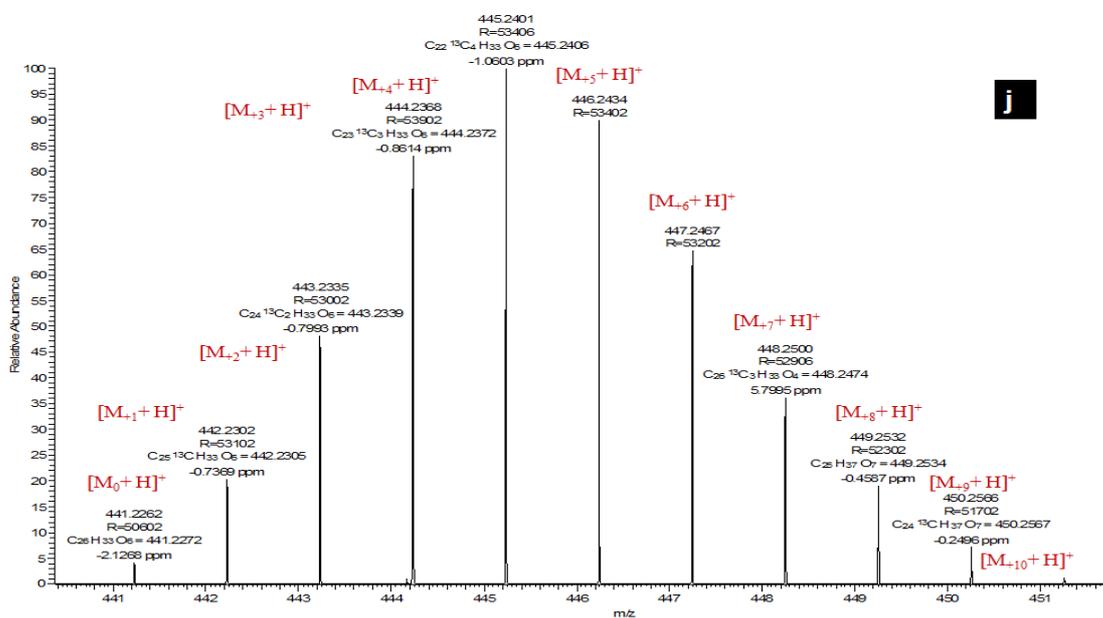

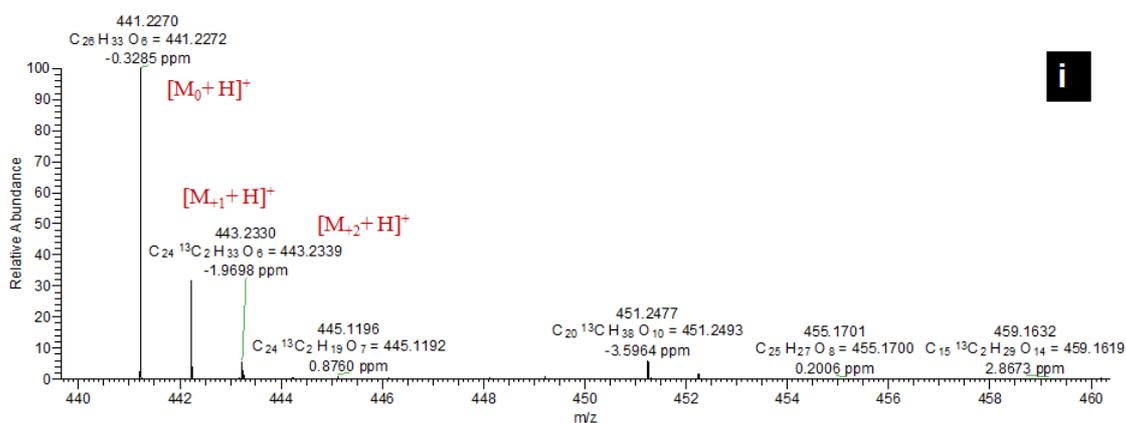

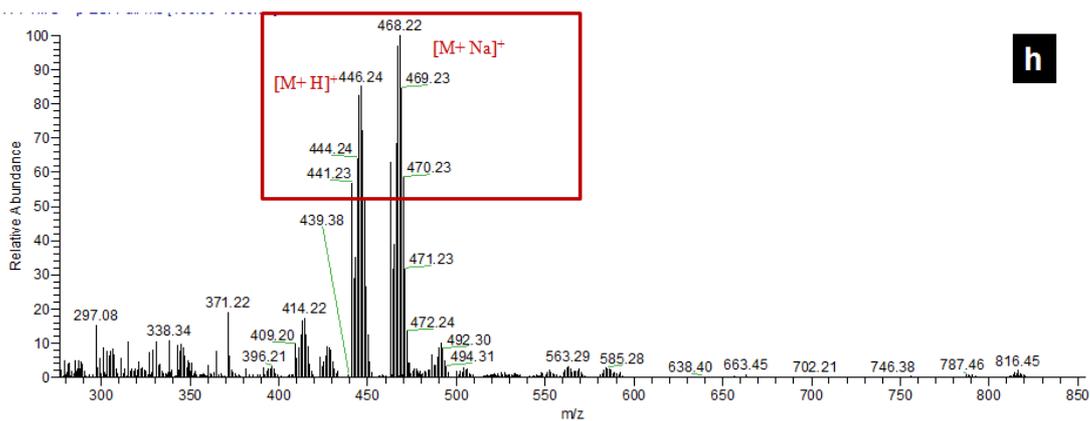

Tandem Mass spectrometry of limonoids and its isotopologues was done in data dependent acquisition mode (PRM) with the protonated molecular ion as a precursor for MS/MS. Isolation window was set to 1, the charge state of 1, NCE 20% and at their corresponding retention time for all the nine limonoids and its isotopologues obtained from cell suspension were set for tandem mass spectrometry. The MS/MS distribution for each isotopologue of four limonoids, azadirachtin A, salannin, salannolacetate and 6-deacetylnimbinene were evaluated individually for different ^{13}C glucose labeling. Consideration of m/z values accurately to fourth decimal for individual isotopologues and isotopomers eliminated the noise generated during MS and MS/MS analysis.

Chapter 4

Study of contribution of MVA and MEP pathway for limonoid formation and cloning of putative genes

Chapter 4: Section A
**Study of the contribution of MVA and MEP
pathway for limonoid formation through
inhibitor study and expression analysis**

4A.1. Introduction

To interrogate the role of a metabolic pathway towards its contribution into another pathway, or role of an intermediate in a pathway, generation of gene mutant strains are essential. Alternatively, use of chemical inhibitors specific to a single biocatalysis step in a pathway help to study the functional contribution of a pathway. Further, use of pathway specific stable isotope intermediates, helps to study the complementation of the pathway for the biosynthesis of a metabolite¹⁻³. Isoprene units of isoprenoids are biosynthesized through two different pathways; mevalonate (MVA) pathway and MEP pathway⁴⁻¹¹. The contribution of one pathway towards a formation of isoprenoid natural product can be studied through chemical inhibition¹⁻³ and subsequent stable isotope labeling approach¹²⁻¹⁵.

Ascomycete species in the rhizosphere, like *Aspergillus terreus*, ubiquitously produce HMGR inhibitors such as mevinolin also called as lovastatin, whose potential to inhibit MVA production was known already over decades and has been used to study isoprenoid biosynthesis¹⁶. It is also used as a cholesterol-lowering agent in mammalian system¹⁶ and also shown to have effect on cell cycle¹⁷. Similarly, 2-C-methyl-D-erythritol 4-phosphate, the reaction intermediate of MEP pathway is mimicked by fosmidomycin¹⁸, hence it inhibits deoxy-xyulose phosphate reductoisomerase¹⁹, the key enzyme involved in non-mevalonate pathway of terpenoid biosynthesis^{20, 21}. Hence, use of these chemical inhibitors helps to study the role and contribution of isoprene biosynthetic pathways towards the formation of different isoprenoids^{1, 3, 21-25} (Figure 4A.1). For example,azole drugs are found to target cytochrome P450 enzymes and down-stream enzymes of sterol biosynthetic pathway. Miconazole, clotrimazole, fucanazole etc. are some of the anti-fungal and chemotherapeutic agents used in medicine²⁶. Miconazole is a N-substituted imidazole which is hypothesized to act by binding to the heterocyclic nitrogen of ferric protoheme of cytochrome P450 enzyme²². Tracing study with stable isotopes has helped in the identification of role of MVA pathway towards limonoid biosynthesis. In the section A of the chapter, the isotope labeling experiments were carried out subsequent to the inhibition of isoprenoid biosynthetic pathways to study the complementation of MVA and MEP pathways for the biosynthesis of limonoids in neem cell culture. Role of miconazole (Figure 4A.2) on the effect of limonoid biosynthetic pathway has also been studied.

Spatial expression levels of genes involved in the rate-limiting step of the MVA and MEP pathways were studied in different tissues of neem tree. Rate-limiting enzyme of MVA pathway is 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase (HMGR), catalyzing the third step of the pathway for the formation of mevalonate from 3-hydroxy-3-methyl-glutaryl-coenzyme A²⁷. Whereas in MEP pathway, rate limiting is the first step of the pathway, catalysed by deoxyxylulose-5-phosphate synthase (DXS)²⁸. It catalyzes the formation of 1-Deoxy-D-xylulose 5-phosphate (DXP) from pyruvate and D-glyceraldehyde 3-phosphate through transketolase-type condensation reaction²⁸. DXS controls the flux through the pathway and overexpression of it have proved the increase in production of isoprenoid end products²⁹. To further comprehend their regulatory roles during the inhibition of MVA pathway, the expression level of the same genes were examined through quantitative polymerase chain reaction (qPCR) experiments.

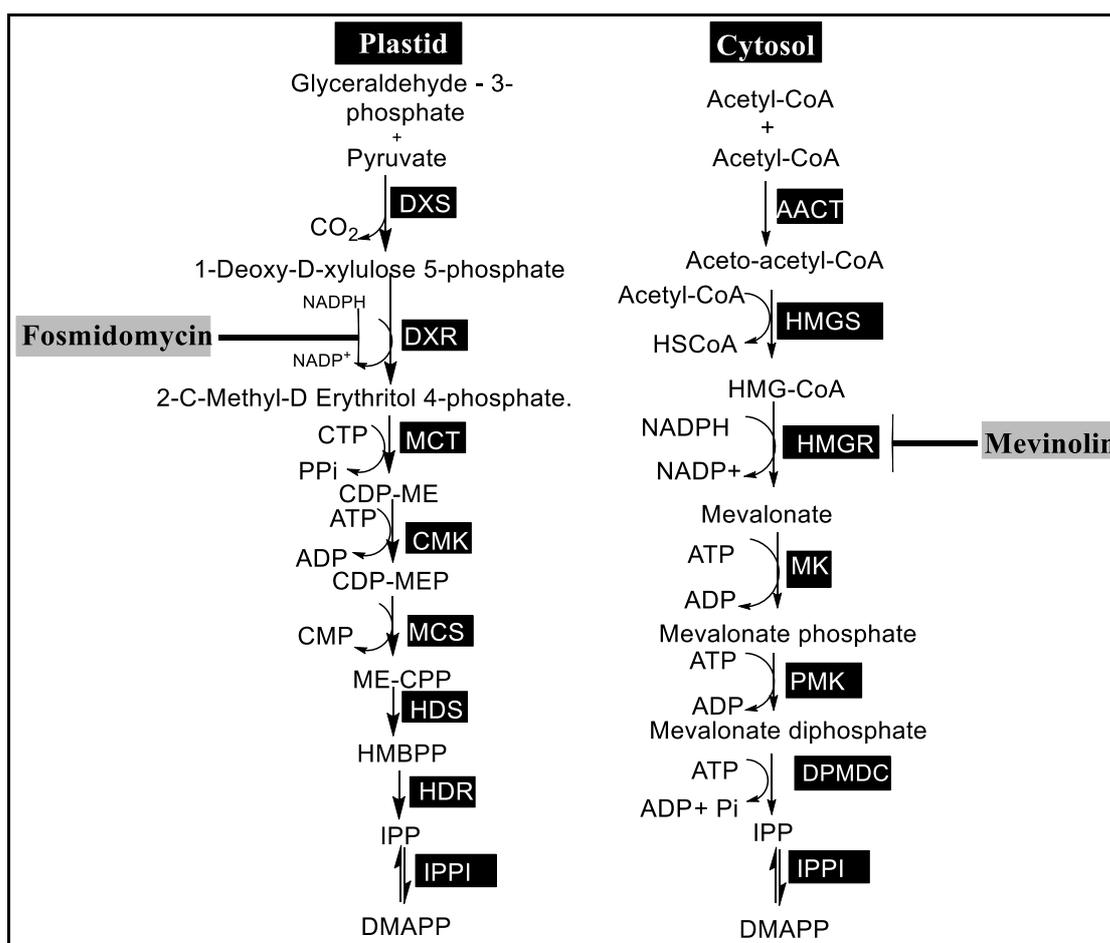

Figure 4A.1. Use of specific pathway inhibitors to study the role of MVA and MEP pathway towards the formation of isoprene unit for a metabolite.

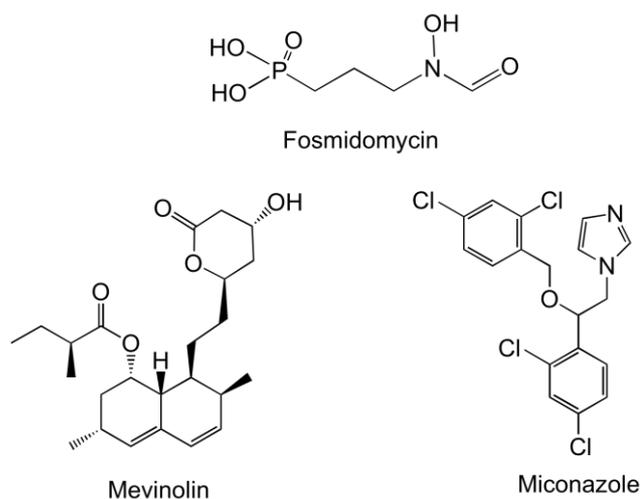

Figure 4A.2. Structure of pathway inhibitors used in this study

4A.2. Results and discussion

4A.2.1 Evaluation of contribution from MVA and MEP pathway for limonoid biosynthesis

4A.2.1.1. Inhibition of MVA pathway with mevinolin

In order to establish the role of MVA and MEP pathways in limonoid biosynthesis, pathway specific chemical inhibition studies were carried out. When suspension cultures were treated with MVA pathway specific inhibitor, mevinolin, it affected both the growth and limonoid content simultaneously in all the concentrations such as 0.05 mM, 0.1 mM, 0.5 mM, and 1 mM (Figure 4A.3 and Figure 4A.4).

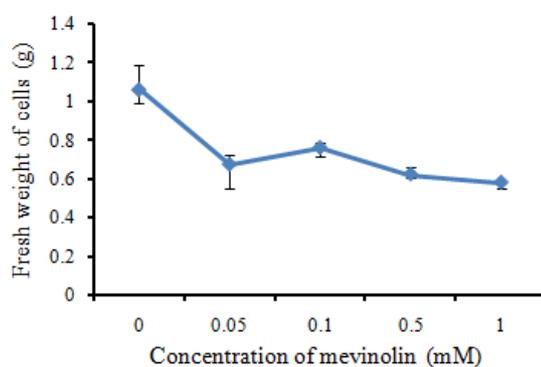

Figure 4A. 3. Effect of inhibitor, mevinolin on growth of cells at different concentrations.

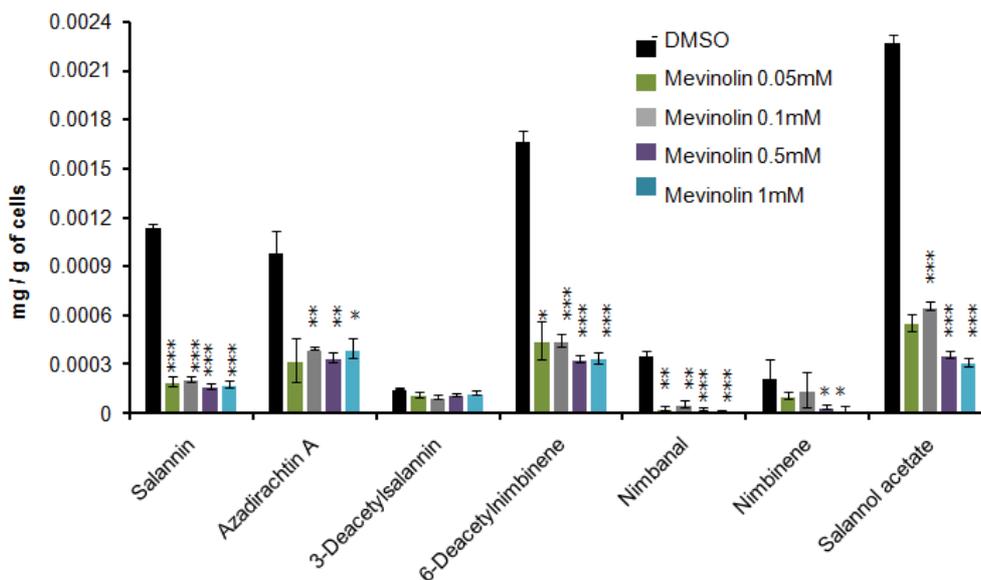

Figure 4A. 4. Effect of different concentrations of mevinolin on limonoid biosynthesis.

4A.2.1.2. Inhibition with miconazole

Miconazole, the inhibitor of cytochrome enzymes affects the growth of cells relatively higher to that of mevinolin at higher doses, 0.5 and 1 mM concentration (Figure 4A.5). The limonoid biosynthesis is also severely affected with miconazole from 0.1 mM concentration and above. The concentration of limonoids biosynthesized is comparatively less in miconazole treated cells to that of the one with mevinolin (Figure 4A.4, Figure 4A.6).

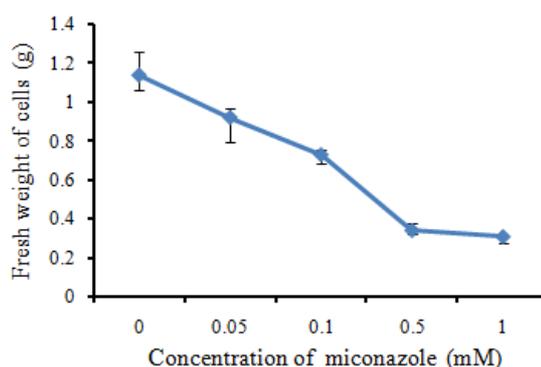

Figure 4A. 5. Effect of inhibitor, miconazole on growth of cells at different concentrations.

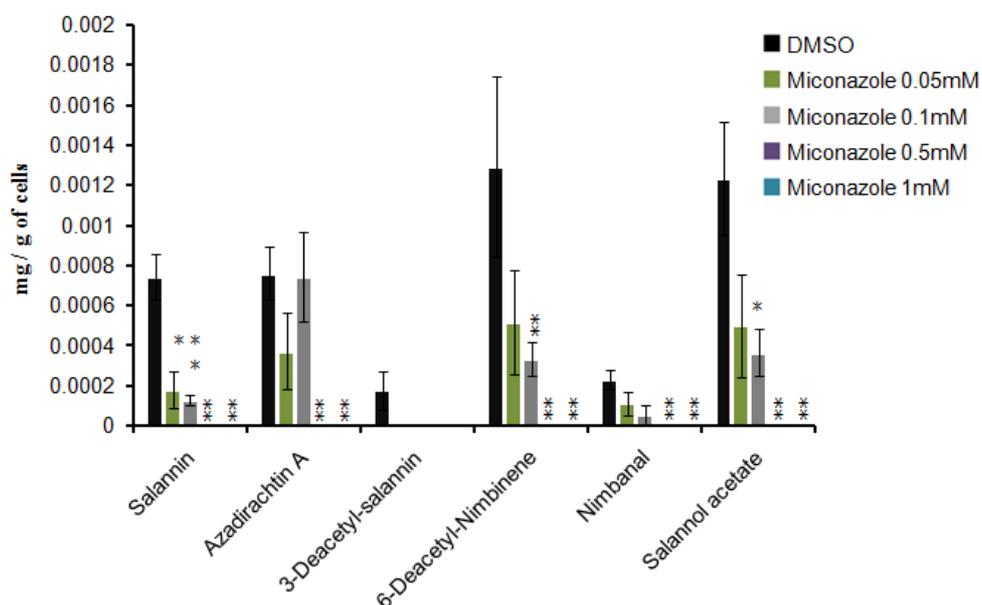

Figure 4A. 6. Effect of different concentrations of miconazole on limonoid biosynthesis

4A.2.1.3. Inhibition of MEP pathway with Fosmidomycin

Cells grown in the presence of the inhibitor fosmidomycin was analyzed for its carotenoid contents. When 0.1 mM fosmidomycin was used to inhibit MEP pathway from the formation of isoprene units, the levels of total carotenoid content was decreased by 78.8% as compared to that of control (Figure 4A.7). Further, the suspension culture showed blanching during the course of exponential growth of the cells in presence of fosmidomycin (Figure 4A.7).

The inhibition studies were also carried out using both inhibitors individually in presence of unlabeled glucose (Glc) and [1,2-¹³C] Glc. Fosmidomycin treatment didn't interfere with the biosynthesis of limonoids as evidenced from the formation of ¹³C limonoid isotopologues whereas in case of inhibition of MVA pathway with mevinolin, drastic decrease in the levels of ¹³C isotopologues was observed (Figure 4A.8). *Ex vivo* labeling studies carried out with ¹³C labeled glucose gives proof of evidence that MVA pathway contributes for the isoprene units of limonoid skeleton and further, inhibitor treatment combined with [1,2-¹³C] Glc labeling experiment shows that blocking the MEP pathway doesn't have any impact on the limonoid biosynthesis. The blanching of

cells due to drop in carotenoids during fosmidomycin inhibition was consistent with the leaf bleaching observed in *Arabidopsis* seedling¹.

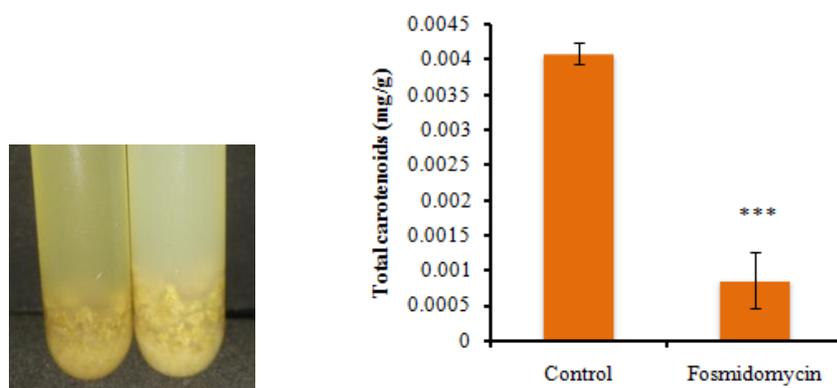

Figure 4A.7. (Left panel) control vs. fosmidomycin treatment (0.1 mM) demonstrating the blanching of color of cell suspension due to drop in carotenoid level: (Right panel) Effect of 0.1 mM fosmidomycin on MEP pathway metabolites: carotenoids

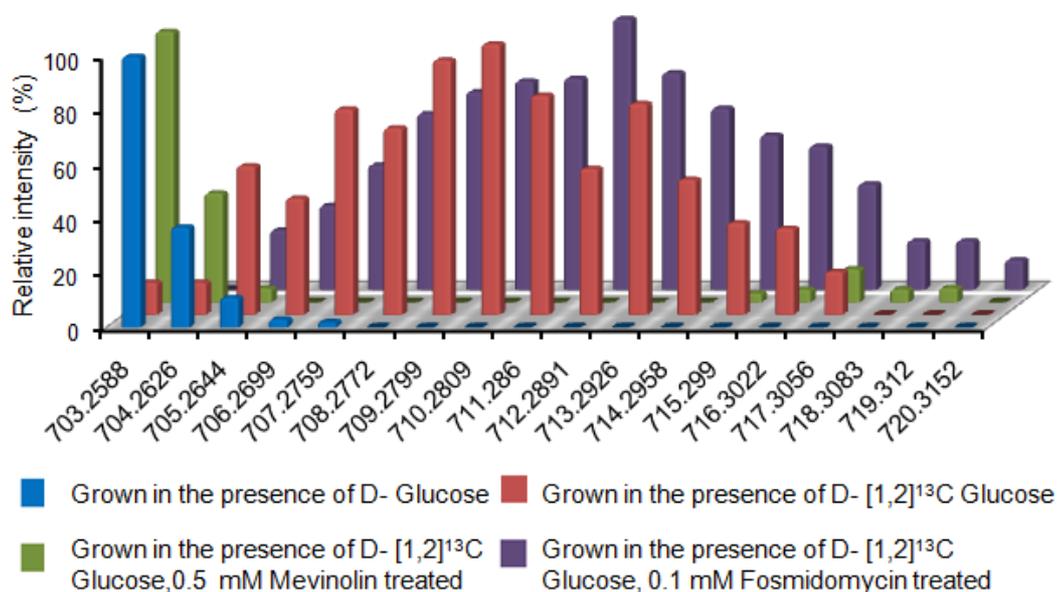

Figure 4A. 8. Chemically inhibited MVA and MEP pathway cells grown in the presence of [1,2-¹³C] Glc to monitor the formation of isotopologues.

4A.2.2. Expression profiling of genes involved in rate limiting step of MVA and MEP pathway

The spatial expression of the genes encoding the rate-limiting enzymes involved in MVA and MEP pathway were studied in different neem tissues such as pericarp and kernel of fruit, leaf, flower, suspension and callus derived from kernel so as to correlate their transcript level to the limonoid biosynthesis. Two transcripts for HMGR and 4 for DXS from MVA and MEP pathway respectively were identified from the neem transcriptome³⁰ and the real-time analysis for all the 6 sequences were performed to determine their expression profile (Figure 4A.9). Even though all the isoforms of HMGR and DXS are expressed, the relative expression of HMGR2 was predominant in all the tissues studied, with the exception of flower (Figure 4A.9). In kernel and pericarp, the expression of DXS transcripts was very low when compared to the HMGR levels. This substantiates the results of ¹³C labeling and inhibitor studies giving proof that MVA pathway plays a major role in limonoid biosynthesis. We also compared the transcript abundance of each gene in different tissues studied (Figure 4A.11). Among the DXS isoforms, DXS1 and DXS3, showed higher level of expression in the leaf tissue whereas, DXS4 level was slightly higher in suspension culture when compared to the leaf tissue. DXS2 and HMGR1 showed comparatively very high level of expression in flower among the tissues studied. The level of expression of HMGR2 was high in kernel and suspension cells relative to the other tissues (Figure 4A.11). Further, to study the effect of pharmacological block of MVA pathway by inhibitor, mevinolin on the transcript level, the real-time PCR profiling was carried out with mevinolin treated neem suspension cells. In comparison to control, the expression profile showed that the relative expression levels of all the seven studied genes of inhibitor-treated cells were comparatively reduced (Figure 4A.10).

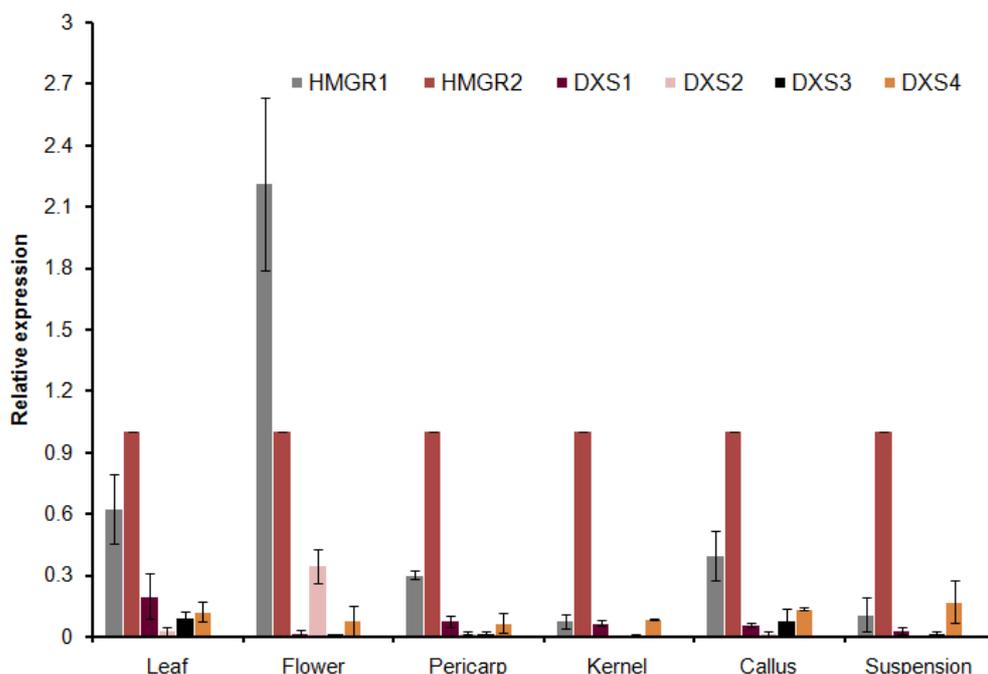

Figure 4A.9. Expression profile of HMGR and DXS genes in various tissues relative to the expression of HMGR2

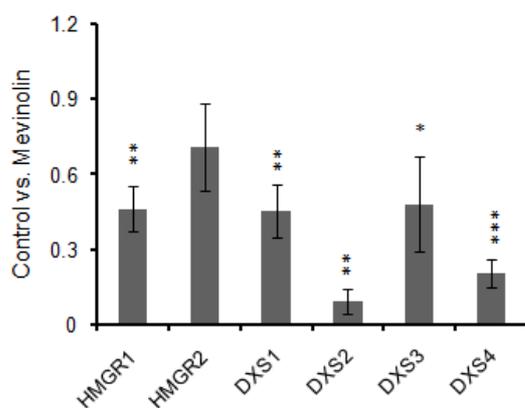

Figure 4A.10. Comparison of expression profile of the studied genes in mevinolin treated cells with respect to control.

Spatial expression profile of genes encoding for the rate-limiting step of isoprene biosynthetic pathway shows that HMGR relative expression level being the highest when compared to MEP pathway genes in all the tissues and cells studied, further bolstering the finding that mevalonate pathway contributes for the isoprene units of limonoid skeleton (Figure 4A.9). Though blocking of MVA pathway at 0.05 mM mevinolin concentration does not affect the growth significantly, the metabolic process of cell and limonoid biosynthesis were decreased, which is also evident from the

marginal reduction in transcript level of HMGR and DXS genes, the rate-limiting steps of both the pathways. Miconazole, the inhibitor of cytochrome enzymes, severely affected limonoid biosynthesis in cell suspension culture when compared to mevinolin (Figure 4A.4, Figure 4A.6), which signifies the fact that cytochrome P450 enzymes play a major role in the limonoid biosynthetic pathway, as most of the downstream steps in the pathway are subsequent oxidation and reduction reactions.

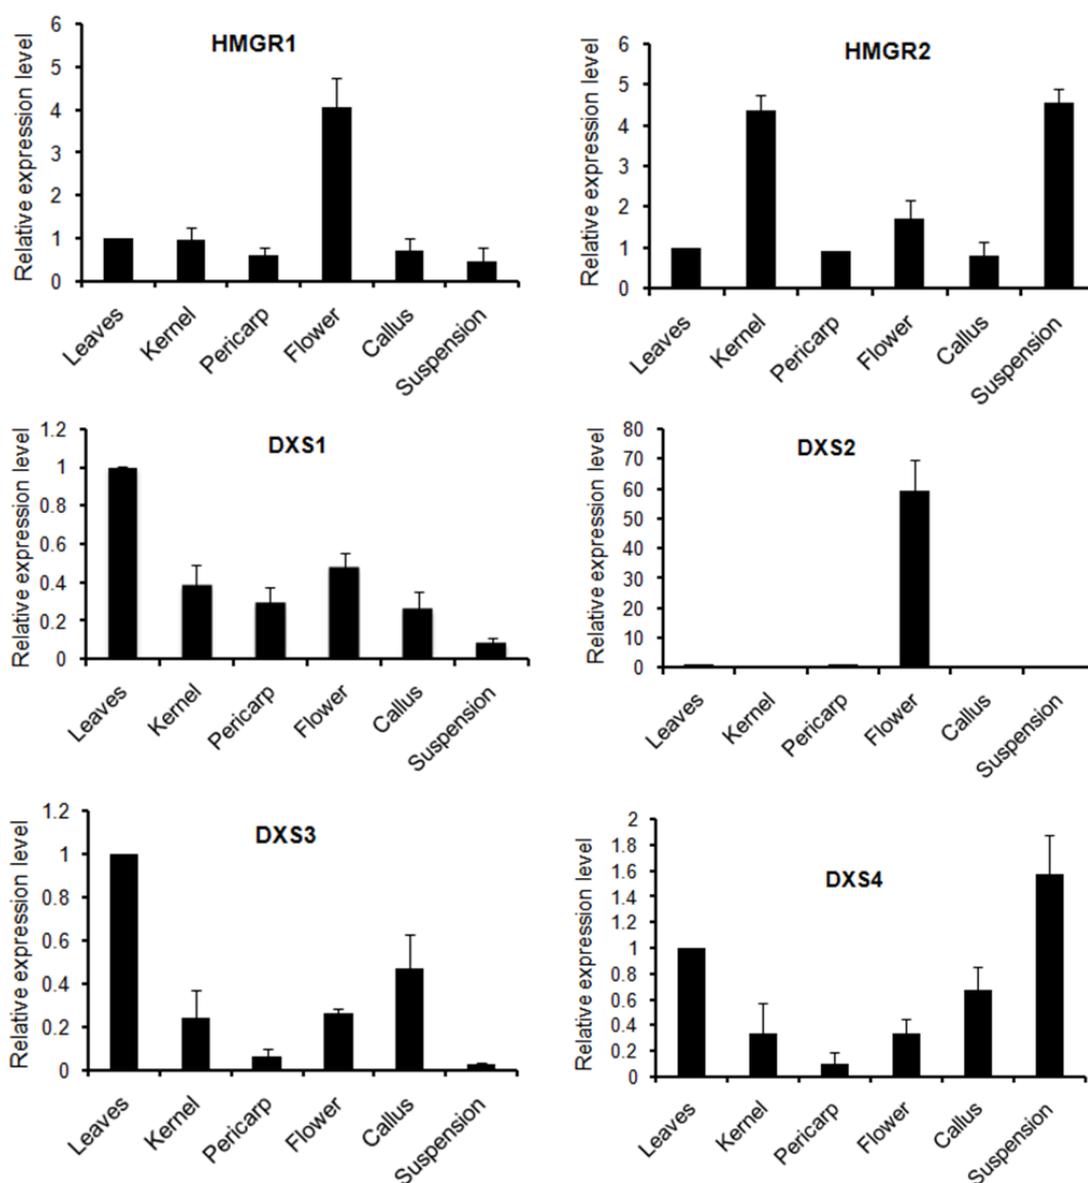

Figure 4A.11. Relative expression level of genes of MVA and MEP pathway encoding for the rate limiting enzymes in different neem tissues. HMGR, 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase; DXS, 1-deoxy-D-xylulose-5-phosphate

4A.3. Conclusion

In the previous chapter, analyses of labeled limonoid extract lead to the identification of signature isoprenoid units involved in azadirachtin and other limonoid biosynthesis, which are found to be formed through mevalonate pathway. This was further confirmed by treatment of cell suspension with mevinolin, a specific inhibitor for MVA pathway, which resulted in drastic decrease in limonoid levels whereas their biosynthesis was unaffected with fosmidomycin mediated plastidial methylerythritol 4-phosphate (MEP) pathway inhibition. This was also conspicuous, as the expression level of genes encoding for the rate-limiting enzyme of MVA pathway, 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGR) was comparatively higher to that of deoxyxylulose-phosphate synthase (DXS) of MEP pathway in different tissues and also in the *in vitro* grown cells.

4A.4. Materials and methods

4A.4.1. Inhibitor Studies

Mevinolin and fosmidomycin (Sigma) were solubilized in DMSO and water respectively, filter sterilized using membrane filter of 0.22 μm pore size (Millipore) and introduced into culture under aseptic conditions. The inhibitor of cytochrome, miconazole was added to the neem suspension cultures at different concentrations along with control for each treatment containing the same solvent in which inhibitors are dissolved. Suspension cultures were treated in triplicates with mevinolin and miconazole at different concentrations such as 0, 0.05, 0.1, 0.5 and 1 mM. Quantification of biomass of cells was done by determining the fresh weight of cells by centrifugation in swinging bucket at $1000 \times g$ (Thermofisher Scientific).

Mevinolin (final concentration 0.05 mM) and fosmidomycin (final concentration 0.1 mM) were added to the cell suspension culture after 2 days of initiation of culture after replacing the cells with fresh media containing no sugars. 3% D-[1,2- ^{13}C] Glc (99% enriched, Cambridge Isotope Lab. Inc., Andover, MA) was supplemented to the 5 mL culture after inhibitor treatment. Two independent experiments were performed each in duplicates. Limonoid extraction was carried out from the cells after ten days of fosmidomycin addition. To further analyze the total carotenoid content, the cells were

frozen in liquid nitrogen, made into fine powder and extracted with acetone in the dark. The extract was centrifuged to remove debris and concentrated to the volume of 3 mL. It was read spectrometrically at 470 nm and the total carotenoid contents were calculated using equation as follows, (described by Lichtenthaler³¹).

$$\begin{aligned}C_a &= 11.24 A_{661.6} - 2.04 A_{644.8} \\C_b &= 20.13 A_{644.8} - 4.19 A_{661.6} \\C_a + C_b &= 7.05 A_{661.6} + 18.09 A_{644.8} \\C_x + C &= 1000 A_{470} - 1.9 C_a - 63.14 C_b / 214\end{aligned}$$

4A.4.2. HRMS Analysis

Analysis of neem limonoids was performed with Thermo Scientific QExactive™ hybrid quadrupole-Orbitrap mass spectrometer associated with Accela 1250 pump and Accela open AS. The conditions of HESI source include capillary temperature of 320 °C, Heater temperature at 350 °C, s-lens RF level of 50, spray voltage of 3.6 kV, spray current of 0.9 μA with sheath gas flow rate of 41, auxiliary gas flow rate of 9 and sweep gas flow rate of 3. Standards as well as the extracted samples were analyzed in positive ionization mode, in full MS-scan with scan range of 100 to 1000 *m/z*. Following were the properties of the scan performed- resolution 70,000, AGC target 1e6, Maximum IT 200 ms. Waters Acquity UPLC BEH C₁₈ column (particle size 1.7 μm, 2.1 X 100 mm) was used as the stationary phase while the solvent system of methanol and water containing 0.1% formic acid served as the mobile phase. The gradient started with 40% methanol (5 min isocratic), it was then increased to 50% (5 min isocratic), followed by 60% methanol for the next 15 minutes and over the next 4 minutes it was isocratic with 65% methanol. It was then increased to 90% methanol for 4 minutes. For the last 2 minutes, it was isocratic with 40% methanol. Constant flow rate of 0.3 mLmin⁻¹ was maintained throughout the run time of 35 min. The chromatograms and mass spectral data were processed by Xcalibur qual browser (version 2.3; Thermo Scientific).

4A.4.3. Quantitative PCR studies

For quantitative PCR analysis, RNA isolation was carried out using Spectrum™ plant total RNA isolation kit (Sigma) from neem callus, suspension, leaf, flower, pericarp, kernel tissues and also from 0.05 mM mevinolin treated suspension cells. RNA

isolation was followed by DNase treatment by using DNase I Amplification Grade kit (Sigma). cDNA was synthesized using SuperScript® III First-Strand Synthesis System (Invitrogen) from 3 µg of total RNA. Through transcriptome analysis, we could identify two ORFs encoding for HMGC_oA reductase (HMGR) and 4 for deoxyxylulose-phosphate synthase (DXS), the enzyme involved in the catalysis of rate-limiting step in MVA and MEP pathway respectively³⁰. qPCR primers were designed for the above 6 transcripts along with the housekeeping genes, elongation initiation factor 4a (ELF4A) and actin (adopted from Rajakani *et al*³²) for normalization (Table 1). Real-time PCR was carried out in AriaMx Realtime PCR system (Agilent Technologies) by using FastStart Universal SYBR Green Master (Roche). The cycling conditions comprised of initial denaturation at 95 °C for 5 min followed by 40 amplification cycles consisting of 95 °C for 15 s and 58 °C for 30 s. All reactions were performed in triplicate assays for 3 biological replicates and relative quantifications were performed using $\Delta\Delta C_T$ method. The two housekeeping genes gave same level of expression and the results were normalized with ELF4A.

Chapter 4: Section B
**Cloning and characterization of putative
acyltransferases in *Azadirachta indica***

4B.1. Introduction

Azadirachta indica A. Juss (Meliaceae) is an indigenous tree of India grown in tropical and sub-tropical regions. Most of the biological properties of neem have been contributed by limonoids, which are highly oxygenated, modified triterpenoids. Limonoids are triterpenes present abundantly in Rutaceae and Meliaceae plant family³³. They are responsible for the bitter principle in citrus and neem, which belongs to Rutaceae and Meliaceae families respectively. Limonoids were named after limonin, the first tetranortriterpenoid isolated from citrus. Limonoids in Meliaceae family are called meliacin-type limonoids^{33, 34}.

Azadirachtin and related compounds are the highly complex limonoids among the numerous limonoids isolated and characterized from neem. In addition to the complex azadirachtin A skeleton, it is highly decorated with different functional groups³⁵. It has two methyl esters, one acetate, a tiglate ester, two tertiary and one secondary hydroxyl groups, along with its dihydrofuran ring linked to another ether ring^{35, 36}.

The information available on limonoid biosynthetic pathway is very limited. Though the upstream steps involved in the formation of the triterpene skeleton has been characterized recently³⁷, different class of enzymes are found and predicted to be involved in the catalyzing this multistep pathway. Some of them include, prenyltransferases³⁷, triterpene cyclases, cytochrome P450 oxido-reductases, and the decoration of the skeleton in the downstream step with functional groups will perhaps be carried out by tigloyltransferases, acetyltransferases etc. These tigloyl and acetyl functional groups are present not only on azadirachtin, but also on the other limonoids, which were hypothesized to be the intermediates in the azadirachtin biosynthetic pathway. Azadirachtin A, salannin, nimbin, nimbinene are the major c-seco limonoids, which exist in, deacetylated form as deacetylazadirachtin A, deacetyl salannin, deacetyl nimbin, deacetyl nimbinene too in the neem tree. Among the major ring intact limonoids of neem, azadiradione and gedunin exist in deacetylated form as nimbocinol and 7-deacetyl gedunin whereas, second major limonoid epoxyazadiradione, the epoxide form of azadiradione has not been found to be exist in its deacetyl form as 7-deacetylepoxiazadiradione (Figure 4B.1). In the present work, screening and identification of different acetyl transferase from neem will be carried out to identify the

acetyltransferase involved in the acetylation of c-seco and ring intact limonoids. This investigation will aid in understanding the functionalization of limonoid skeleton.

The large diversity of secondary metabolites is achieved by elaboration of the basic skeletons, modifying enzymes that catalyze decarboxylation, oxidation/reduction, hydroxylation, glycosylation, methylation, and acylation reactions. One of the common forms of modification of secondary metabolite is the acylation of oxygen-containing substrates to produce esters³⁸. Either acyl-sugars, acylated acylcarrier proteins or acyl-activated coenzyme A thioesters serve as active acyl donors and the enzymes that catalyze these acylations on diverse group of plant metabolites belong to large protein family named as BAHD which utilize CoA thioesters as acyl donor³⁸. The BAHD acyltransferase family was named according to the first letter of each of the first four biochemically characterized enzymes of this family as follows, benzylalcohol O-acetyltransferase, anthocyanin O-hydroxycinnamoyltransferase, anthranilate N-hydroxycinnamoyl/benzoyltransferase from *Dianthus caryophyllus* and deacetylvindoline 4-O-acetyltransferase from *Catharanthus roseus*, (BEAT, AHCT, HCBT and DAT respectively)³⁸⁻⁴⁴. Acetylation has been found to serve as a protective group in the multistep biosynthetic reactions of noscapine pathway in opium poppy⁴⁵. Acyltransferases, highly specific for each subsequent step of taxol biosynthetic pathway have been discovered in yew tree (*Taxus sp.*). Taxa-4(20),11(12)-dien-5 α -ol O-acetyltransferase (TAT)⁴⁶⁻⁴⁸ catalyzes the first acylation step of taxol biosynthetic pathway followed by taxane 2 α -O-benzoyltransferase (TBT)⁴⁹ that act on 2-debenzoyl taxoid-type intermediate to form 10-deacetylbaccatin III which in turn is converted to baccatin III regiospecifically, by 10 β -acetyltransferase (DBAT)⁵⁰. Further, 3-amino-3-phenylpropanoyltransferase (BAPT) was instrumental in 13-O-acylation of baccatin III with β -phenylalanoyl CoA as the acyl donor to form N-debenzoyl-2'-deoxytaxol⁵¹. Next is the last and final acylation step of taxol biosynthesis and it is catalyzed by taxoid C 13-side-chain N-benzoyltransferase (DBTNBT) using benzoyl-CoA as acyl donor⁵². Taxusin, a prominent side-route metabolite of taxol pathway of *Taxus* has also been found to be formed due to the catalytic activity of two taxoid-O-acetyl transferases⁵³. Acetyl-CoA-dependent acyltransferases have been found to catalyze crucial steps in several alkaloid pathways such as salutaridinol acetyltransferase in morphine biosynthetic pathway in *Papaver somniferum*^{54, 55}, vinorine synthase in ajmaline

biosynthetic pathway of medicinal plant *Rauvolfia serpentina*^{56, 57} and in *Catharanthus roseus*, the biosynthesis of vindoline, a biogenetic precursor of the dimeric alkaloids vinblastine and vincristine is catalyzed by DAT⁴⁴ whereas a different enzyme minovincinine-19-Oacetyltransferase (MAT) catalyzes the formation of minovincinine⁵⁸.

On the other hand, acyltransferases such as monoterpene acetyltransferases of *Lavandula x intermedia* is capable of acting on different monoterpenes (lavandulol, geraniol, nerol) as substrate to form its corresponding acetates⁵⁹. These acetyltransferases act on fragrance and flavor metabolites in flower and fruit respectively. The geraniol/citronellol acetyltransferase in rose flower catalyzes the formation of geraniol and citronellol⁶⁰. Range of alcohol substrates from short to medium straight chain (C3–C10), branched chain, aromatic and terpene alcohols are acylated by apple alcohol acyl transferases⁶¹. Similarly, a BAHD acyltransferases of petunia have been characterized for its catalytic ability to act efficiently on phenylpropanoid substrates coniferyl alcohol but can also catalyze different alcohol substrate⁶². In plants, phospholipid:sterol acyltransferase (PSAT) is capable of transferring acyl donors to both phospholipids and sterols⁶³, whereas in *Arabidopsis*, saturated fatty acyl-coenzyme A are transferred to sterols by sterol O-acyltransferase⁶⁴. Thus diverse acyl coA donors such as acetyl-CoA, β -phenylalanine-CoA, malonyl-CoA, tiglyl-CoA, anthraniloyl-CoA, benzoyl-CoA⁶⁵ and (hydroxy) cinnamoyl-CoA are utilized by plant BAHD acyltransferases⁶⁶.

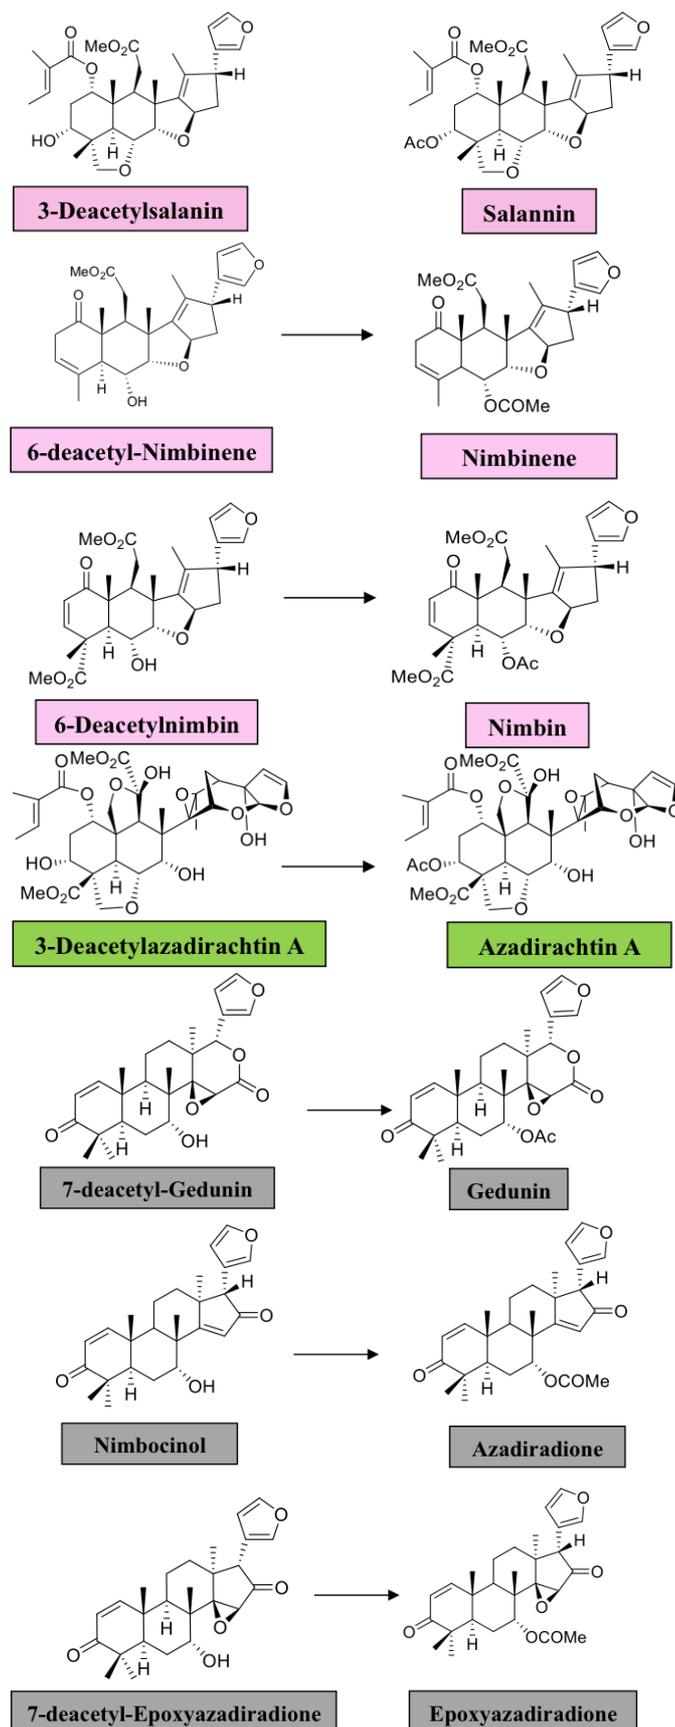

Figure 4B.1. Possible acetylation sites in some of the most abundant limonoids in neem

4B.2. Results and discussion

4B.2.1. Phylogenetic analysis

The predicted neem acyltransferases grouped with hypothetical acyltransferases of citrus, which belongs to Rutaceae family, which is another source of limonoid group of natural products. The clade of comprising of acyltransferases of neem and citrus are close to the clade of the enzymes involved in acetyl transfer reactions in taxol biosynthetic pathway of *Taxus* (Figure 4B.2).

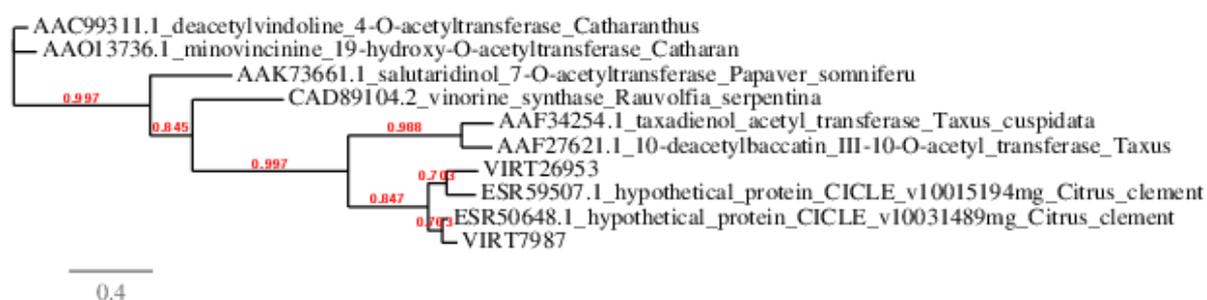

Figure 4B.2. Phylogenetic analysis of acetyltransferases of plant BAHD family

4B.2.2. RNA isolation

The RNA isolated from pericarp and leaves were checked for its concentration and quality spectrometrically by verifying its 260/280 and 260/230 ratios. RNA analyzed through electrophoresis evidenced clear 28S rRNA, 18S rRNA and 5S rRNA as three bands along with mRNA (Figure 4B.3).

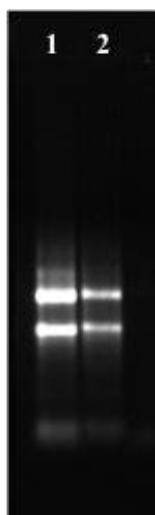

Figure 4B.3. Total RNA isolation, **Lane 1:** Neem fruit pericarp, **Lane 2:** Neem leaf, (RNA electrophoresed in 1% agarose gel)

4B.2.3. Cloning of acyltransferase 1 (AiACT1)

AiACT1 transcript sequence (Master control_17413) information was used for designing full-length primers. The Open Reading Frame (ORF) was found to be 1353 bp, which may encode a polypeptide of 450 amino acids. It showed 72% identity with annotated citrus acyltransferase sequence, which belongs to the BAHD family of plant acyltransferase. Deduced protein was calculated to have a theoretical molecular weight of 51.19 kDa and pI of 8.1. The deduced sequence was found to have HTICD catalytic domain and DFGWG conserved motif as of plant BAHD acyltransferases, which has HXXXD, a catalytic domain and DFGWG conserved motif respectively.

Amplicon of 1.6 Kbp obtained was amplified from cDNA obtained from neem fruit pericarp RNA (Figure 4B.4). The AiACT1 ORF was cloned into pET32a vector frame with N-terminal His-6 tag for affinity purification *E.coli* Rosetta Gammi 2 (DE3) cells. Positive clones were screened using T7 Forward and reverse primers by colony PCR (Figure 4B.5) and the presence of insert was confirmed by subjecting the plasmid to restriction digestion. The cloned insert was confirmed for its sequence and orientation using DNA sequencing using T7 Forward and reverse primers, which confirmed the size of ORF as 1353 bp.

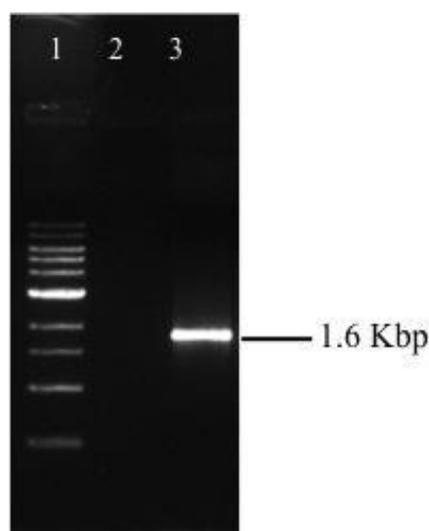

Figure 4B.4. AiACT1 full-length ORF amplification, **Lane 1:** 1 Kb DNA ladder, **Lane 2:** No template control (NTC), **Lane 3:** PCR of AiACT1 full-length primers with pericarp cDNA as template (DNA electrophoresed in 1% agarose gel)

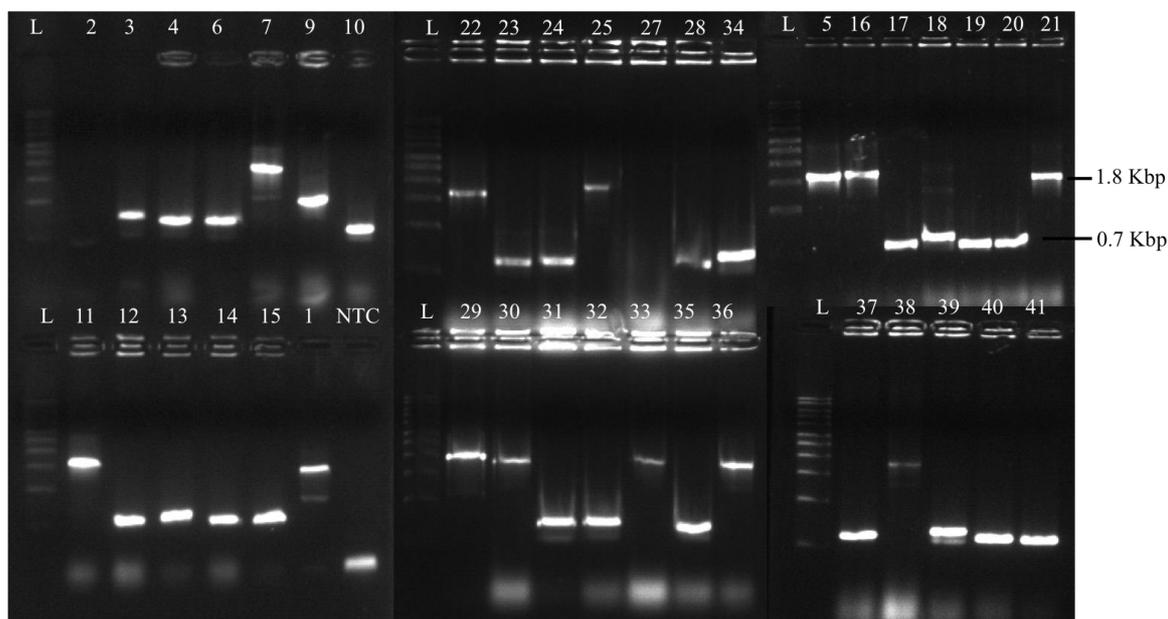

Figure 4B.5. Colony PCR screening of full-length ORF of AiACT1 in pET32a, PCR performed with T7 promoter and T7 reverse primer **Lane L:** 1 Kb DNA ladder, **NTC:** No template control (negative control), **positive colonies 1, 5, 7, 11, 16, 21, 22, 25, 29, 30, 33, 36, 38:** Showed amplicon of ~ 1.8 Kbp, others colonies showed ~ 0.7 Kbp amplicon- self-ligated colonies. (DNA electrophoresed in 1% agarose gel)

4B.2.4. Cloning of Acyltransferase 2 (AiACT2)

AiACT2 transcript sequence (Master control_99887) information was used for designing full-length primers. The Open Reading Frame (ORF) was found to be 1395 bp, which may encode a polypeptide of 464 amino acids. It showed 83% identity with annotated citrus acyltransferase sequence, which belongs to BAHD family of plant acyltransferase. Deduced protein was calculated to have a theoretical molecular weight of 51.35 kDa and pI of 7.9. The deduced sequence was found to have HTMSD catalytic domain and DFGWG conserved motif as of other BAHD acyltransferases, which has HXXXD, a catalytic domain and DFGWG conserved motif respectively.

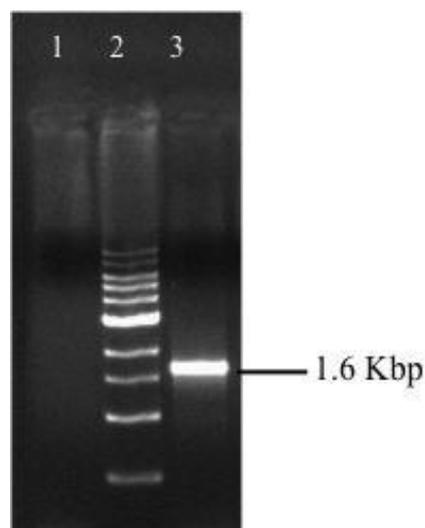

Figure 4B.6. AiACT2 full length ORF amplification, **Lane 1:** 1 Kb DNA ladder, **Lane 2:** No template control (NTC), **Lane 3:** PCR of AiACT2 full-length primers with leaf cDNA as template (DNA electrophoresed in 1% agarose gel).

Amplicon of 1.6 Kbp obtained was amplified from cDNA obtained from neem leaf RNA (Figure 4B.6). The AiACT2 ORF was cloned into pET32a vector frame with N-terminal His6 tag for affinity purification in *E.coli* Rosetta 2 (DE3) cells. Positive clones were screened using T7 Forward and reverse primers by colony PCR (Figure 4B.7) and the presence of insert was confirmed by subjecting the plasmid to restriction digestion. The cloned insert was confirmed for its sequence and orientation using DNA sequencing using T7 Forward and reverse primers, which confirmed the size of ORF as 1395 bp.

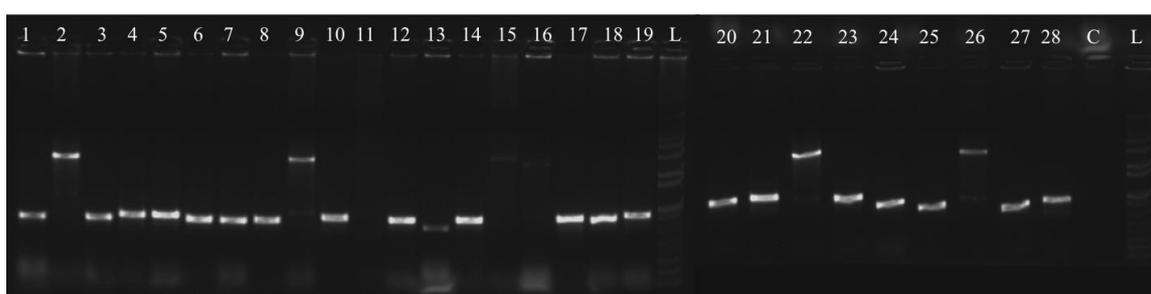

Figure 4B.7. Colony PCR screening of full-length ORF of AiACT2 in pET32a, PCR performed with T7 promoter and T7 reverse primer **Lane L:** 1 Kb DNA ladder, **C:** No template control (negative control), **colony 2, 9, 15, 16, 22, 26:** Showed amplicon of ~ 1.8 Kbp, others colonies showed ~ 0.7 Kbp amplicon- self-ligated colonies. (DNA electrophoresed in 1% agarose gel)

4B.2.5. Codon analysis of AiACT1 and AiACT2

Codon analysis of AiACT1 showed that 2 rare codons of bacteria such as CCC and GGA were present in the sequence. In AiACT2, eight rare codons of bacterial system were present. Hence, Rosetta 2 (DE3) and Rosetta Gammi 2 (DE3), which contains 7 bacterial rare codons have been used as a host system for expression of the recombinant AiACT proteins.

Figure 4B.8. Codon analysis for AiACT1 and AiACT2 sequences

4B.2.6. Expression and purification of AiACT1

Expression was carried out in Rosetta gammi 2 (DE3). Initially different imidazole gradients were tried, washing the unbound protein fractions were carried out starting with 5 mM, and 10 mM imidazole containing buffer. Later at 20 mM imidazole, the unbound protein eluted. Recombinant AiACT1 protein was eluted in 50 mM imidazole containing buffer. Further, 100 mM, 150 mM, 200 mM, 250 mM imidazole containing buffer were used, in which no more elutions were seen. The protein fractions show a band at 72 kDa for AiACT1 on a 12% SDS-PAGE (Figure 4B.9). Desalted proteins were flash-frozen and stored at -80 °C until use. Enzyme assay with studied limonoid substrates did not showed any product formation.

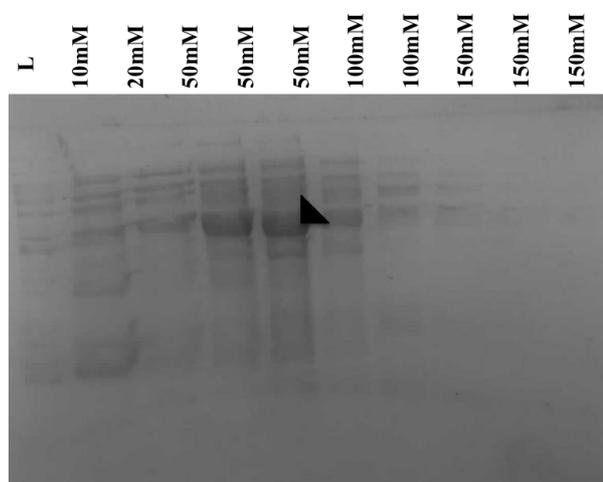

Figure 4B.9. SDS-PAGE analysis of eluted AiACT1 protein fractions from Ni-NTA agarose column. The **arrow** shows **72 kDa protein** corresponding to **AiACT1**

4B.2.7. Expression and purification of AiACT2

Expression was carried out in Rosetta 2 (DE3). The protein eluted in 50 mM imidazole containing buffer. The protein fractions show a band at 72 kDa for AiACT1 on a 12% SDS-PAGE (Figure 4B.10). 20 L of culture gave final yield of 0.5 mg of protein

of 50% purity as seen in Figure 4B.10. This low level of expression may be due to several rare codons present in AiACT2 sequence (Figure 4B.8). Desalted proteins were flash-frozen and stored at -80 °C until use. Enzyme assay with studied limonoid substrates did not showed any product formation.

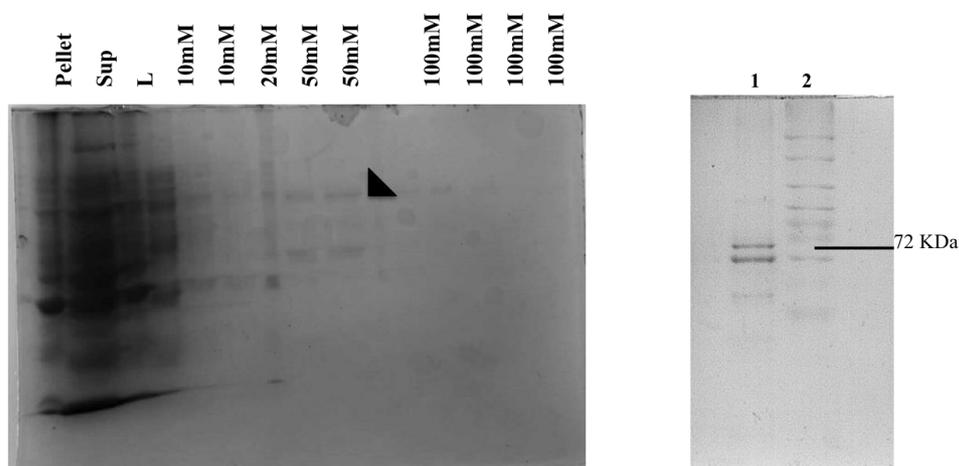

Figure 4B.10. SDS-PAGE analysis of eluted AiACT2 protein fractions from Ni-NTA agarose column (*Left*), **Lane 1**, The purified protein obtained with 50% purity seen at 72 KDa, **Lane 2**, Protein Ladder (*Right*). The **arrow** shows **72 KDa protein** corresponding to AiACT2.

Since the expression level of AiACT2 was very less in Rosetta 2 (DE3) cells, the plasmid was transformed into other expression cells such as Rosetta gammi 2 (DE3), B834 (DE3) LysS and Arctic express cells expressed. Faint band was observed with Rosetta gammi 2 (DE3), B834 (DE3) expression cells upon induction, whereas no desired protein was observed with Arctic express cells which indicates that the expression of ACT2 is facilitated by rare codons encoded in these bacterial strains.

4B.2.8. Cloning, expression of AiACT1 in *Saccharomyces cerevisiae* and identification of its function

The ORF of AiACT1 was amplified using accuprime DNA polymerase (Figure 4B.11) and cloned into pYES2/CT vector for expression of active protein under the control of T7-RNA polymerase promoter in INVSc yeast cell. Positive clones were screened by colony PCR using T7 Forward and CYC reverse primers (Figure 4B.12). The protein was expressed by inducing with 2% galactose in CSM-Ura dropout media and grown for 24 hrs (as mentioned in methods section). To check the activity of enzymes the substrates were added to the media and incubated for 8 hrs. Due to the

activity of ATF gene⁶⁷ (alcohol acetyltransferase) in yeast, substrates such as benzyl alcohol, hexanol, heptanol, farnesol, nerol gave very little conversion of < 0.5 conversion into its acetylated forms such as benzyl acetate, hexyl acetate, heptyl acetate, farnesyl acetate, neryl acetate (Figure 4B. 15C) respectively and more activity was observed towards geraniol comparatively⁶⁸. In case of geraniol, it was reduced into citronellol (Figure 4B.15B), due to the activity of old yellow enzyme (OYE) gene of *Saccharomyces cerevisiae*^{67, 69, 70} whereas interconversion into different terpenes such as linalool, nerol, terpeniol, geraniol, citronellol has been identified variably in different yeast strains as evident from the literature^{69, 71}. Hence, conversion of geraniol to citronellol, citronellol acetate and geraniol acetate was observed in control yeast cells. Farnesyl acetate peak was 1.5 fold higher than the control, uninduced cells (Figure 4B.15A). To further check the activity of the gene on sterol triterpenes, saponified yeast cells were extracted for triterpenes with n-hexane and no activity was observed on the yeast triterpene alcohols.

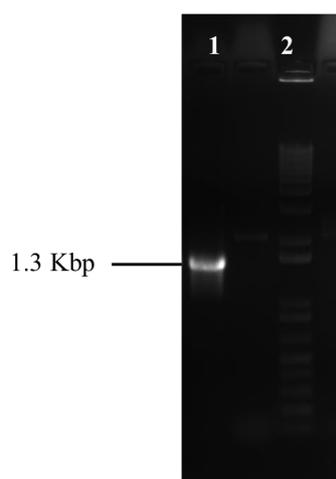

Figure 4B.11. AiACT1 full-length ORF amplification, **Lane 1:** PCR using AiACT1 full-length primers for cloning into pYES2/CT, **Lane 2:** 1 Kb +DNA ladder

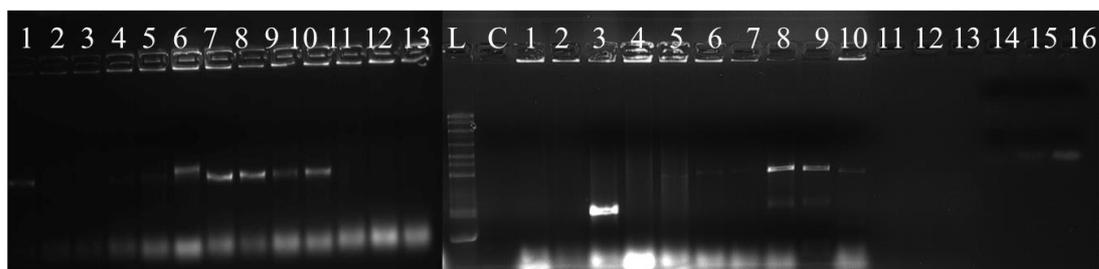

Figure 4B.12. Colony PCR screening of full-length ORF of AiACT1 in pYES2/CT in 2 transformation experiments (13 colonies and 16 colonies screened from 2 transformation

reactions), PCR performed with T7 forward and CYC reverse primer **Lane L**: 1 Kb DNA ladder. **Lane C**: No template control. Positive colonies are seen as 1.3 Kbp. Positive colonies are 6A, 7A, 8A, 9A, 10A, 8B, 9B, 10B.

4B.2.9. Cloning and expression of AiACT2 in *Saccharomyces cerevisiae* and identification of its function

The ORF of AiACT2 was amplified using accuprime DNA polymerase (Figure 4B.13) and cloned into pYES2/CT vector for expression of active protein under the control of T7-RNA polymerase promoter in INVSc yeast cell. Positive clones were screened by colony PCR using T7 Forward and CYC reverse primers (Figure 4B.14). The protein was expressed by inducing with 2% galactose in CSM-Ura dropout media as mentioned in methods section and grown for 24 hrs. To check the activity of enzymes the substrates were added to the media and incubated for 8 hrs. Farnesyl acetate peak was 1.5 fold higher than the control, uninduced cells (Figure 4B.15A). No activity was seen for any of the other screened substrates.

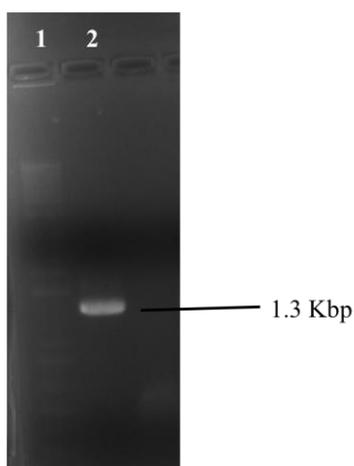

Figure 4B.13. AiACT2 full-length ORF amplification, **Lane 1**: 1 Kb +DNA ladder, **Lane 2**: PCR using AiACT2 full-length primers for cloning into pYES2/CT

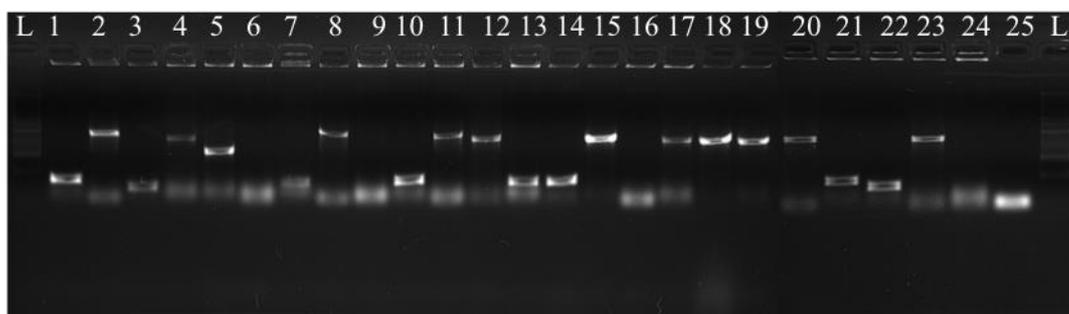

Figure 4B.14. Colony PCR screening of full-length ORF of AiACT2 in pYES2/CT, PCR performed with T7 forward and CYC reverse primer **Lane L:** 1 Kb DNA ladder. Positive colonies are seen as 1.3 Kbp and self-ligated at 0.3 Kbp.

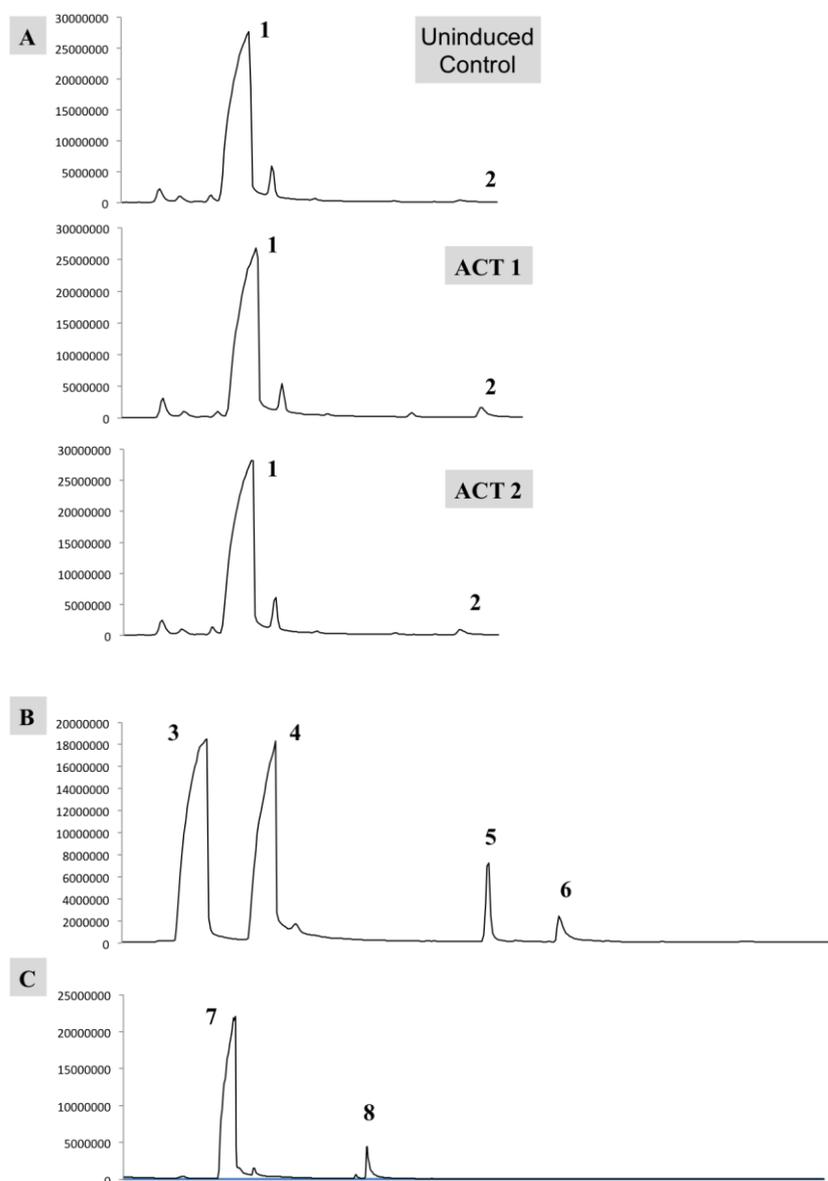

Figure 4B.15. GC-MS chromatogram showing the conversion of various alcohol substrates into acetyl group by in yeast system. 1. Farnesol, 2. Farnesyl acetate, 3. Citronellol, 4. Geraniol, 5. Citronellol acetate, 6. Geraniol acetate, 7. Nerol, 8. Neryl acetate, B and C represents control, uninduced yeast cells.

4B.3. Conclusion

The neem acyltransferases AiACT1 and AiACT2 were cloned and expressed in bacterial and yeast expression system. They didn't show activity on ring intact and c-

seco limonoids. Its activity on aliphatic and terpene alcohols were not significant. Hence, the result shows that these enzymes may act on the low abundance or labile pathway intermediates of limonoid biosynthetic pathway. This is also evident from the transcriptome analysis that their expression was high in pericarp and leaf tissues, which are enriched with triterpenoid intermediates of less complex structure. These tissues are high in the biosynthesis of ring intact limonoids, hence their activity may exist on the conversion of protolimonoids into the intermediate limonoids.

4B.4. Materials and methods

4B.4.1. Bacterial Strains and Plasmids used in the Study

Escherichia coli Mach1™ T1^R (ThermoFisher Scientific, USA)

Escherichia coli Rosetta 2 (DE3) (Novagen)

Escherichia coli Rosetta Gammi 2 (DE3) (Novagen)

INVSc1, *S. cerevisiae* Yeast Strain (ThermoFisher Scientific, USA)

pET-32a expression vector (Novagen)

pYES2/CT Yeast Expression Vector (ThermoFisher Scientific, USA)

4B.4.2. Kits and reagents used in the study

SuperScript® III Reverse Transcriptase (ThermoFisher Scientific, USA)

JumpStart™ Taq DNA Polymerase (Sigma-Aldrich, USA)

Platinum® PCR SuperMix (Invitrogen)

AccuPrime™ Pfx DNA Polymerase (ThermoFisher Scientific, USA)

PureLink™ Quick Gel Extraction and PCR Purification Combo Kit (ThermoFisher Scientific, USA)

GenElute™ PCR Clean-Up Kit (Sigma-Aldrich)

GenElute™ Plasmid Miniprep Kit (Sigma-Aldrich)

GelRed™ (Biotium Inc., USA)

Restriction enzymes (New England Biolabs, USA)

T4 DNA ligase (Invitrogen/ Life Technologies, USA)

T4 DNA ligase (New England Biolabs, USA)

S.c. EasyComp™ Transformation Kit (ThermoFisher Scientific, USA)

FastStart Universal SYBR Green Master (Rox) (Roche, Switzerland)

DNase I Amplification Grade Kit (Sigma-Aldrich, USA)

4B.4.3. Phylogenetic analysis of acyltransferase of neem

A phylogenetic tree was constructed for the two genes from neem, in comparison with acyltransferases from closely related species. Multiple sequence alignments were performed using software Clustal Omega and phylogenetic tree was generated using the nearest neighbour joining method through Phylogeny.fr.

4B.4.4. RNA isolation and cDNA synthesis

Neem leaves and fruits collected from the neem tree in NCL campus during the month of April-May and were frozen in liquid nitrogen and stored at -80 °C. 100 mg of finely ground-powdered tissue was used for RNA isolation. The materials were treated with 0.1% Diethyl pyrocarbonate (DEPC) (Sigma). RNA isolation was carried out using Spectrum™ plant total RNA isolation kit (Sigma) from neem leaves and fruit pericarp. Three µg of total RNA was used for first strand cDNA synthesis using SuperScript® III Reverse Transcription Kit (ThermoFisher Scientific) and the synthesized cDNA, was stored at -20 °C till further use.

4B.4.5. Sequence analysis

After identification of the genes involved in triterpene biosynthesis, sequences were analyzed by NCBI GenBank database. Sense strand ORFs were selected using online ORF finder tool, and based on the ORFs, primers were designed, which contained sites for restriction enzyme at both the ends, for cloning full-length ORF in expression vector using OligoAnalyzer tool.

Name	5'-3' Primer sequence	Size in bp
AiACT1-FP	AGCTGCGATATCATGTCATTA <u>AAATTCCTCAAGT</u>	35
AiACT1-RP	AGCCGTCTCGAGCTAAAGCTTGCAA <u>AAATAT</u>	30
AiACT2-FP	AATTGAGGATCCATGCCACCATCACA <u>ACCACCA</u>	33
AiACT2-RP	TTACTTGCGGCCGCTTACAGAGCAGATGCTATGA	34

Table 4B.1. Primer sequence for isolation of full length ORF of the genes acyltransferases involved in limonoid biosynthesis. (The underlined sequence represents the recognition site for restriction enzyme).

4B.4.6. Isolation and cloning of ORF of Acyltransferase 1 (AiACT1)

Synthesized cDNA was used for PCR reaction using Platinum® PCR SuperMix (Invitrogen) using the PCR program: Initial denaturation at 94 °C for 3 min, followed by 35 cycles at 94 °C for 30 sec, 54 °C for 30 sec, 72 °C for 1 min 30 sec followed by final extension at 72 °C for 3 min. PCR product of 1.6 Kbp was cloned into pET32a expression vector after digesting both with EcorV and XhoI restriction sites. Restriction digested vector and insert were subjected to ligation using T4 DNA ligase (NEB) at 16 °C incubation overnight. The ligation mixture was transformed into Mach1 chemical competent cells by applying heat shock at 42 °C, then plated on Luria Bertani agar with 50 µg/mL of ampicillin and incubated at 37 °C overnight. From 7 positive clones of colony PCR, plasmid isolation was carried out. To check for the sequence in the correct vector frame of the vector, it was sequenced with T7 forward and T7 terminator reverse primers.

4B.4.7. Isolation and cloning of ORF of Acyltransferase 2 (AiACT2)

Synthesized cDNA was used for PCR reaction using Platinum® PCR SuperMix (Invitrogen) using the PCR program: Initial denaturation at 94 °C for 3 min, followed by 35 cycles at 94 °C for 30 sec, 57 °C for 30 sec, 72 °C for 1 min 30 sec followed by final extension at 72 °C for 3 min. PCR product of 1.6 Kbp was cloned into pET32a expression vector after digesting both with BamHI and NotI restriction sites. Restriction digested vector was subjected to alkaline phosphatase, calf intestinal (CIP) (NEB) treatment to remove the phosphate at the 5'- and 3' terminal, in order to prevent the self-ligation of vector during ligation reaction. Insert and above said treated vector were subjected to ligation using T4 DNA ligase (Invitrogen) at 16 °C incubation overnight. The ligation mixture was transformed into Mach1 chemical competent cells by applying heat shock at 42 °C, then plated on Luria Bertani agar with 50 µg/mL of ampicillin and incubated at 37 °C overnight. Positive clones were screened by colony PCR with T7 promoter and T7 terminator primers.

4B.4.8. Expression and purification of AiACT1

Expression was carried out in Rosetta gammi 2 DE3, cells were grown in Terrific Broth at 37 °C and induced with IPTG at a final concentration of 1mM and incubated for

12 hours at 16 °C. The culture was then centrifuged at 4000 × g for 20 minutes and the cell pellet (5 g/L) was re-suspended in 10 mL/g of cell pellet of Lysis buffer (25 mM MOPSO, 100 mM NaCl, 0.5% CHAPS, 0.1% Triton x-100, pH 7.4, 10% v/v Glycerol) with 1 mg/mL concentration of lysozyme, 1mM PMSF incubated on ice for 30 minutes. After the incubation period, the cells were sonicated with a pulse of 30 sec ON and 30 sec OFF for 10 cycles. The crude lysate obtained upon centrifugation at 5,000 × g for 10 minutes at 4 °C was subjected to Ni-NTA column (2 mL resin /g cell pellet). The unbound proteins were eliminated by using wash buffer (25 mM MOPSO, 100 mM NaCl, pH 7.4, 20 mM Imidazole, 10% v/v Glycerol). The protein was finally eluted out in the elution buffer (25 mM MOPSO, 100 mM NaCl, pH 7.4, 50 mM Imidazole, 10% v/v Glycerol) each. Protein fractions (after checking on 12% SDS gel) were pooled together, desalted and purified using Amicon centrifugal filter units with desalting buffer (25 mM MOPSO, pH 7.4, 10% v/v Glycerol). The desalted proteins were estimated using Bradford reagent (Bio-Rad) and a Bovine Serum Albumin standard.

4B.4.9. Expression and purification of AiACT2

Expression was carried out in Rosetta 2 DE3, cells were grown in Terrific Broth at 37 °C and induced with IPTG at a final concentration of 1 mM and incubated for 12 hours at 16 °C. The culture was then centrifuged at 4000 × g for 20 minutes and the cell pellet (5 g/L) was re-suspended in 10 mL/g of cell pellet of Lysis buffer (25 mM MOPSO, 100 mM NaCl, 0.5% CHAPS, 0.1% Triton x-100, pH 7.4, 10% v/v Glycerol) with 1 mg/mL concentration of lysozyme, 0.5 mM PMSF incubated on ice for 30 minutes. After the incubation period, the cells were sonicated with a pulse of 30 sec ON and 30 sec OFF for 10 cycles. The crude lysate obtained upon centrifugation at 5,000 × g for 10 minutes at 4 °C was subjected to Ni-NTA column (2 mL resin / g cell pellet). The unbound proteins were eliminated by using wash buffer (25 mM MOPSO, 100 mM NaCl, pH 7.4, 20 mM Imidazole, 10% v/v Glycerol). The protein was finally eluted out in the elution buffer (25 mM MOPSO, 100 mM NaCl, pH 7.4, 50 mM Imidazole, 10% v/v Glycerol) each. Protein fractions (after checking on 12 % SDS gel) were pooled together and desalted, purified using Amicon centrifugal filter units with desalting buffer (25 mM MOPSO, pH 7.4, 10% v/v Glycerol). The desalted proteins were estimated using Bradford reagent (Bio-Rad) and a Bovine Serum Albumin standard.

4B.4.10. Enzyme assays

Reaction buffer used for the assay was 25 mM MOPSO, 300 mM NaCl, pH 7.4, 10% v/v Glycerol, 3 mM DTT. 400 μ M of substrates (3-deacetylsalannin, 3-deacetylazadirachtin, 7-deaceetylgedunin, 7-deacetylepoxызadiradione, nimbocinol, 6-deacetylnimbin, 6-deacetylnimbinene), 400 μ M of acetyl-CoA and the purified protein were incubated at 25 °C for 3 hrs and extracted thrice with n-hexane.

4B.4.11. Characterization of assay products

Analysis of neem limonoids was performed with HRMS, Thermo Scientific QExactive™ hybrid quadrupole-Orbitrap mass spectrometer associated with Accela 1250 pump and Accela open (as mentioned earlier). The conditions of HESI source include capillary temperature of 320 °C, Heater temperature at 350 °C, s-lens RF level of 50, Spray voltage of 3.6 kV, spray current of 0.9 μ A with sheath gas flow rate of 41, Auxiliary gas flow rate of 9 and sweep gas flow rate of 3. Standards as well as the extracted samples were analyzed in positive ionization mode, in full MS-scan with scan range of 100 to 1000 *m/z*. Following were the properties of the scan performed- resolution 70,000, AGC target 1e6, Maximum IT 200 ms. Waters Acquity UPLC BEH C₁₈ column (particle size 1.7 μ m, 2.1 X 100 mm) was used as the stationary phase while the solvent system of methanol and water containing 0.1% formic acid served as the mobile phase. The method used was 90% methanol and 10% water. Constant flow rate of 0.3 mL min⁻¹ was maintained throughout the run time of 10 min. The chromatograms and mass spectral data were processed by Xcalibur qual browser (version 2.3; Thermo Scientific).

4B.4.12. Cloning into yeast system

The following primer sequences were designed for cloning the genes into yeast pYES2/CT.

Name	5'-3' Primer sequence	Size in bp
AiACT1 YRS -FP	AGCTGCGGATCCAAAACAATGTCTATGTCATTAA AATTCCTCAAGT	47
AiACT1 YRS -RP	AGCCGTCTCGAGCTAAAGCTTGCAAAATAT	33

AiACT2 YRS -FP	AATTGAGGATCCAA AAACAATGTCTATGCCACCAT CACAACCACCA	45
AiACT2 YRS -RP	TTACTT GCGGCCGCTT CAGAGCAGATGCTATGA	33

Table 4B.2. Primer sequence for isolation of full length ORF of the acyltransferases genes involved in limonoid biosynthesis. (The underlined sequence represents the recognition site for restriction enzyme, and Kozak sequence shown in italics).

4B.4.13. AiACT1 Cloning and expression in yeast system

PCR reaction was performed using Accuprime® Pfx DNA Polymerase (ThermoFisher Scientific, USA) in the following PCR program: Initial denaturation at 94 °C for 3 min, followed by 35 cycles at 94 °C for 30 sec, 54 °C for 30 sec, 68 °C for 1 min 30 sec followed by final extension at 68 °C for 3 min. PCR product of 1.3 Kbp was cloned into pYES2/CT expression vector (Invitrogen™) after digesting both with BamHI and XhoI restriction sites. Restriction digested vector was subjected to alkaline phosphatase, calf intestinal (CIP) (NEB) treatment to remove the phosphate at the 5′- and 3′ terminal, in order to prevent the self-ligation of vector during ligation reaction. Then, the vector and insert were subjected to ligation using T4 DNA ligase (NEB) at 16 °C incubation overnight. The ligation mixture was transformed into Mach1 competent cells and plated on LB agar and incubated overnight at 37 °C. Positive clones were screened by colony PCR with T7 forward and CYC reverse primers. From 6 positive clones of colony PCR, plasmid isolation was carried out. To check for the sequence in the correct vector frame of the vector, it was sequenced with T7 forward and CYC reverse primers. The plasmid was again transformed into Invsc1 competent cells *S. c.* EasyComp™ Transformation Kit and, plated on 2% glucose containing complete supplement mixture (CSM) agar without Uracil (as selection marker) and incubated for 24 hours at 30 °C.

The transformed colony was inoculated into 10 mL liquid CSM-URA media with 2% glucose and incubated for 24 hours at 30 °C. It was further transferred into 100 mL CSM-URA dropout media with 2% glucose by maintaining OD₆₀₀ of 0.4 in the freshly initiated culture. Further, the cells were inoculated into 1 L CSM-URA dropout induction media with 2% galactose followed by centrifugation at 1500 × g for 10 min for pelleting the cells. It was incubated at 180 rpm at 30 °C in rotary shaker for 24 hrs. The cells were incubated with 1 mg of different substrates such as hexanol, geraniol,

farnesol, nerol, linalool, dihydromyrcenol, benzyl alcohol for 8 hrs at the pH 6. The incubated cells were extracted with n-Hexane twice and reduced to final volume of 0.5 mL and analyzed using GC-MS.

4B.4.14. AiACT2 Cloning and expression in yeast system

PCR reaction was performed using Accuprime® Pfx DNA Polymerase (ThermoFisher Scientific, USA) in the following PCR program: Initial denaturation at 94 °C for 3 min, followed by 35 cycles at 94 °C for 30 sec, 54 °C for 30 sec, 68 °C for 1 min 30 sec followed by final extension at 68 °C for 3 min. PCR product of 1.3 Kbp was cloned into pYES2/CT expression vector after digesting both with BamHI and NotI restriction sites. Restriction digested vector was subjected to alkaline phosphatase, calf intestinal (CIP) (NEB) treatment to remove the phosphate at the 5' and 3' terminal, in order to prevent the self-ligation of vector during ligation reaction. Then, the vector and insert were subjected to ligation using T4 DNA ligase (NEB) at 16 °C incubation overnight. The ligation mixture was transformed into Mach1 competent cells and plated on LB agar and incubated overnight at 37 °C. Positive clones were screened by colony PCR with T7 forward and CYC reverse primers. From 6 positive clones of colony PCR, plasmid isolation was carried out. To check for the sequence in the correct vector frame of the vector, it was sequenced with T7 forward and CYC reverse primers. The plasmid was again transformed into Invsc1 competent cells using *S. c.* EasyComp™ Transformation Kit and, plated on CSM-URA dropout agar and incubated overnight at 30 °C.

The transformed colony was inoculated into 10 mL liquid CSM-URA dropout media with 2% glucose and incubated for 24 hours at 30 °C. It was further transferred into 100 mL CSM-URA media with 2% glucose by maintaining OD₆₀₀ of 0.4 in the freshly initiated culture. Further, the cells were inoculated into 1 L CSM-URA dropout induction media with 2% galactose followed by centrifugation at 1500 × g for 10 min for pelleting the cells. It was incubated at 180 rpm at 30 °C in rotary shaker for 24 hrs. The cells were incubated with 1 mg of different substrates such as hexanol, heptanol, geraniol, farnesol, nerol, linalool, dihydromyrcenol for 8 hrs at the pH 6. The incubated cells were extracted with n-Hexane twice and reduced to final volume of 0.5 mL and analyzed using GC-MS as mentioned below.

For the isolation of triterpenes, saponification was done with 10 % KOH in 80 % ethanol at 70°C for 2 h, and then extracted thrice with equal volumes of n-hexane. Hexane extract was concentrated to dryness and reconstituted in 0.5 mL hexane.

4B.4.15. GC-MS analysis

It was analyzed by a 7890A Gas Chromatography system coupled to MS 5975C (Agilent Technologies). Separation of monoterpenes, sesquiterpenes and other alcohol, their acetates was performed by using Restek Rtx-5 (30 m × 0.25 mm × 0.25 μm) capillary column with helium as a carrier gas at a flow rate of 1 mL min⁻¹. The extract of 1 μL was injected in splitless mode. The temperature program was set at 50 °C for 2 min, followed by a temperature gradient from 50 °C to 250 °C at a ramping rate of 10 °C/min, and held at 250 °C for 10 min. The molecules were identified by matching the acquired mass spectra with the reference library (National Institute of Standards and Technology). For the separation of triterpenes of yeast, the following method was used, 80 °C for 2 min, followed by a temperature gradient from 80 °C to 290 °C at a ramping rate of 20 °C/min, and held at 290 °C for 20 min.

Thesis summary

Neem tree, is one of the well-known Indian medicinal plants, used for its healing property from ancient past. Its remarkable insecticidal and various pharmacological activities are contributed by terpenoids called limonoids. Over 250 compounds have been isolated and characterized from neem seeds, around 150 of these being limonoids. They belong to triterpene class of natural product. Terpenes are composed of isoprene units (C₅), isopentenyl diphosphate (IPP) and its isomer dimethylallyl pyrophosphate (DMAPP), the repetitive motives in the terpenoids. The isoprene building blocks are biosynthesized through MVA and MEP pathway localized in cytosol and plastid respectively in plant cell. Though mono-, di-, tetra-terpenes are biosynthesized through MEP pathway, and sesqui- and tri-terpenes through MVA pathway, exchange of isoprene units occur either uni- or bi-directionally between the compartments under certain conditions in plants. And also, for the immense biosynthesis of specialized metabolites and their sequestration, plants have evolved specialized anatomical appendages and cell types such as trichomes, idioblast cells, laticifers, resin cells, secretory cells, gland or cavities. These structures help plants for the efficient utilization of secondary metabolites for defense or pollinator attraction and also to protect the adverse and detrimental effect for the producing plant. Apart from the specialized cells, vacuoles and vesicles are important intracellular organelles, which are known to accumulate secondary metabolites, thereby aiding in prevention of self-toxicity for the host cells. Synthesis of a complex secondary metabolite requires multiple organelles such as chloroplast, cytosol, endoplasmic reticulum, vesicles, vacuoles and nucleus. Hence, the biosynthetic machinery that plant cell employs for terpene production and thereby its storage remains unexplored for this wonder tree, which is examined through this study.

In the present study, histochemical analysis of different tissues has been carried out, to study the limonoid localization in cellular and subcellular compartments. Metabolite profiling of the isolated organelle was performed which showed the individual localization of different class of metabolites across different tissues of neem. It suggested that laticifers are rich in basic limonoids and oil bodies are found to be the major source of C-seco limonoids in pericarp and kernel of neem fruit respectively, whereas limonoids exist in abundance in idioblast vacuoles in pericarp and leaf tissues. Average number of idioblasts per mm² of tissue was comparatively high in pericarp to that of leaf, which matched with the abundance of limonoids in these tissues

respectively. In addition, flower was found to contain flavonoids in pollen, and sesquiterpenes in secretory vesicles.

Neem callus and suspension culture capable of limonoid biosynthesis was established from surface sterilized fresh neem cotyledons. Limonoid profiling of callus and suspension culture showed the stable biosynthesis of nine C-seco limonoids. Limonoid biosynthesis in the cell suspension at different stages of subculturing were characterized by using [1,6-¹³C] Glc label as carbon source for the cells, which showed that limonoids biosynthesis was decreased in cells obtained from callus subcultured 22 times as compared to callus subcultured 3 times.

¹³C labeled isotopologues of glucose were used to study limonoid biosynthetic pathway in neem cell suspension. In order to identify the signature fragment of azadirachtin A generated through ESI-MS, fragments generated from MS/MS of azadirachtin derivatives such as azadirachtin B, H, 3-deacetylazadirachtin A, epi-azadirachtin D, vepaol were studied comparatively at different normalized collision energies. The plausible fragmentation pathway for azadirachtin A has been proposed showing the structure-fragment relationship. This helped in tandem mass spectrometry (MS/MS) analyses of labeled limonoid extract, which lead to the identification of signature isoprenoid units involved in azadirachtin and other limonoid biosynthesis. Therefore, the isoprene units contributed for limonoid skeleton biosynthesis are found to be formed through mevalonate (MVA) pathway from this study.

Chemical inhibition of the pathways along with concomitant ¹³C Glc labeling was carried out to study the complementation of both the pathways. Treatment of cell suspension with mevinolin, a specific inhibitor for MVA pathway, resulted in drastic decrease in limonoid levels whereas their biosynthesis was unaffected with fosmidomycin mediated plastidial methylerythritol 4-phosphate (MEP) pathway inhibition. This was also conspicuous, as the expression level of genes encoding for the rate-limiting enzyme of MVA pathway, 3-hydroxy-3-methyl-glutaryl-coenzyme A reductase (HMGR) was comparatively higher to that of deoxyxylulose-phosphate synthase (DXS) of MEP pathway in different tissues and also in the *in vitro* grown cells as evident from real time PCR analysis. The genes encoding for the enzymes mediating the downstream steps of limonoid biosynthesis need to be studied. In order to understand limonoid diversity in neem, putative acyltransferase ORFs were selected from neem transcriptome for cloning. The selected acyltransferases matched with BAHD family of

plant acetyltransferases, which transfers acyl group from CoA to natural products. The two full length ORFs were cloned and expressed in bacterial system and due to low level of expression in bacteria, it was further cloned into yeast system. Different limonoid substrates, mono-, sesquiterpene alcohols were used as substrate, but the activity for acylation of the studied natural products was not seen. Hence, the result shows that these enzymes may act on the low abundance or labile pathway intermediates of limonoid biosynthetic pathway, which needs to be studied further.

Curriculum Vitae

Ms. T. AARTHY

Senior Research Fellow,
Chemical Biology Unit,
Division of Organic Chemistry,
CSIR-National Chemical Laboratory,
Dr. Homi Bhabha Road,
Pune-411008.
Maharashtra, India.
Email: bio.arty@gmail.com
Mob: +91 9049519412

Summary

- Chemical Biologist with research experience in the study of primary and specialized metabolism in plants
- Research background in biochemistry and molecular biology; conversant with the techniques for the study of Plant Natural Product metabolic pathways.
- Interested in natural product biochemistry.

Current position

- **Research Fellow**, CSIR-National Chemical Laboratory, Division of Organic Chemistry, Pune, India (Since July 2012)
- **Research Supervisor**: Dr. H. V. Thulasiram
- **Ph. D. Thesis Title**: Limonoid Biosynthesis in *Azadirachta indica*: Characterization of pathway genes and analysis of labeled metabolites through stable isotope feeding

Education

Bachelor of Technology (B.Tech) Biotechnology, 2011, Agricultural college and Research Institute, Tamil Nadu Agricultural University, Coimbatore, India
Cumulative Grade Point Average - 8.89 / 10

Class	Institution	Board/ University	Year of Completion	Marks %
X	Jaycees Matriculation Higher Secondary School, Kangayam, Tamil Nadu	Matriculation	2005	88.81
XII (Bio/Chem/ Phy/Maths)	Jaycees Matriculation Higher Secondary School, Kangayam, Tamil Nadu	State Board	2007	94.08

Thesis highlights

- Stable isotope labeling study to trace the flow of carbons en route from primary metabolic pathway to triterpenoid biosynthesis.
- Study of role and complementation of metabolic pathways through chemical inhibition and mRNA expression levels.

- Localization of different classes of natural product in specialized cells and organelles in different plant tissues.
- Cloning and characterization of genes involved in secondary metabolite biosynthesis.

Projects / training before PhD programme

- Biotechnology Industrial Training Programme 2011-12 at Indo-American Hybrid Seeds Private Limited, Bengaluru, India in the project entitled ‘Induced mutagenesis and detection of somoclonal variants in *Philodendron xanadu* plants regenerated through direct and indirect shoot organogenesis’ organized by Biotechnology Consortium India Limited (BCIL), New Delhi, India
- As part a of B.Tech degree, worked on ‘Screening of high β -carotene in pearl millet genotypes and its segregating generation through RP-HPLC for developing mapping population for enhanced β -carotene’ at Centre for Plant Molecular Biology and Biotechnology, Tamil Nadu Agricultural University, Coimbatore, India
- Completed a short term project on ‘Genotyping Analysis of Tomato Hybrids using DNA and Protein Finger Printing’ at Indo-American Hybrid Seeds Private Limited, Bangalore, India
- Undergone summer Training at Center for Research in Medical Entomology (CRME), Madurai, India

Presentations /Workshops

- Genetically Modified Bacteria Mediated Food Preservation (Poster) National symposium on Recent Trends in Food Processing on World Food Day 2008, Tamil Nadu Agricultural University, Coimbatore, India
- “Treatment of Cancer by Gene Silencing”, Poster presentation, Glimpses of future prospects in Biotechnology, Rasipuram, India
- Organised National Level technical Symposium BIOCONCORRENZA-2010, Tamil Nadu Agricultural University, Coimbatore, India
- Workshop on Molecular Biology Techniques for Detection of Infectious diseases at Thiruchirapalli, India.
- Participated in National Level technical Symposium BIOCONCORRENZA-2011, Tamil Nadu Agricultural University, Coimbatore, India.
- Fingerprinting of COH(M)5 Maize Hybrid and its Parental lines for Genetic purity Assessment (Poster) World Congress of Biotechnology, 21 - 23 March 2011, Hyderabad, India.
- Screening of high β carotene in pearl millet genotypes and its segregating generation through RP-HPLC for developing mapping population for enhanced β -carotene (Poster) World Congress of Biotechnology, 21 - 23 March 2011, Hyderabad, India.

- Participated in “Indo-Mexico workshop on Biotechnology: Beyond borders” organized by CSIR-NCL, Pune and CINVESTAV, Mexico, October, 2013.
- “*In vivo* tracer study for biosynthesis of limonoids in *Azadirachta indica* cell culture”, Poster presentation, Peptide Engineering Meeting-7 (PEM7), (December 5-7, 2015) IISER Pune
- “*In vivo* tracer study for biosynthesis of limonoids in *Azadirachta indica* cell culture”, Poster presentation, International Conference on Biotechnology and Bioinformatics (February 5-7, 2016), Pune
- “*In vivo* tracer study for biosynthesis of limonoids in *Azadirachta indica* cell culture”, Poster presentation, National Science Day, CSIR-NCL, Pune, (February 25-26, 2016), **Best poster award in ‘National Science Day Celebrations 2016’**
- Participated in workshop on “Transcriptome Data Analysis” (August 16-18, 2016), NCL Innovation Park, Pune.
- “Study of limonoid biosynthesis and cellular localization in *Azadirachta indica*”, Poster presentation, EMBO conference on Micro and metabolic regulators in plants, Thiruvananthapuram, Kerala, India (February 01-04, 2017)

Educational accomplishments

- “**NCL-RF-GUPTA-PARDESHI-SAINANI award**” for “Best Published Research Paper in Biological Sciences” for the year 2018 in National chemical Laboratory.
- Secured All India Rank 17 in Category A in Biotechnology Eligibility Test for Junior Research Fellowship (BET-JRF) 2012, conducted by Department of Biotechnology (DBT), Government of India
- Secured All India Rank Graduate Aptitude Test in Engineering (GATE) 2012 in Biotechnology (BT) Percentile Score- 99.6
- Graduate Record Examination (GRE) 2011 Score-1270 (Verbal-590, Quants-680)
- Received awards for academic excellence for being a School topper in class XI and XII
- Award for securing first mark in Biology and Chemistry in class XII.

Technical skills

Molecular biology:

- RNA extraction, reverse transcription, Real time (Quantitative) and endpoint PCR, DNA purification
- DNA fingerprinting studies
- Cloning in bacterial and yeast system: primers designing, restriction digestions, ligations, competent cell preparation, transformation

Biochemistry:

- Heterologous protein expression and affinity column purification
- Whole cell mediated biotransformation of natural products
- Microsomal and *in vitro* enzyme assays
- Enzyme kinetics

Analytical methods:

- Chromatography (Thin layer, HPLC, Gas chromatography),
- Mass spectrometry (LC-ESI-Orbitrap, GC-QTOF, GC-MS)
- Spectrophotometric techniques
- Sound theoretical knowledge and interpretation of most the analytical techniques

Metabolic profiling:

- Metabolite extraction from bacterial, fungal, plant and animal systems.
- Metabolic profiling, fingerprinting, metabolite quantification.

Cell biology and Histochemistry

- Bacterial and yeast cell culture
- Microscopy: Epi-fluorescence, confocal and light microscopy.
- Tissue sectioning, staining

Plant cell culture:

- Plant cell and tissue culture
- Protoplast isolation and culture

Other Skills:

- **IT:** extensive knowledge on standard office software, ChembiDraw, CorelDraw, Photoshop, Graphpad Prism, Origin Pro, Endnote, Mendeley.
- **Languages:** Tamil (mother tongue), English (fluent), Hindi (moderate).

Declaration

I hereby declare that the above mentioned details are true and accurate to the best of my Knowledge and belief.

T. Aarthy
